Taking a history from a spouse or relative is essential. Patients may tend to down play or deny symptoms (anosognosia) or constantly look to the relative for answers (the ‘head turning sign’). See Box 22.29 for key elements in taking a history.

Examination

Conversation with the patient during history taking may be as revealing as formal cognitive assessment but many patients hide deficits well behind an intact social façade.

Bedside cognitive assessment

The mini-mental state examination (MMSE) (see p. 1155) is commonly used to assess cognitive function but has its limitations, such as relative insensitivity to milder cognitive impairment and to frontal lobe dysfunction.

The Addenbrooke’s Cognitive Examination (ACE) is a tool developed to address the deficiencies of the MMSE but is short enough to use in clinical practice.

It is useful to ask patients to give an account of recent news events to assess episodic memory.

Individual cognitive domains can be tested separately in detail, e.g. clock drawing for parietal lobe function, naming and reading tasks for language function, verbal fluency, cognitive estimates and stop-go tasks for frontal lobe function (frontal assessment battery – FAB).

Neurodegenerative diseases

Box 22.29 Taking a dementia history

- **Memory:**
 - Is (s)he repetitive, e.g. with questions?
 - Is there a temporal gradient of amnesia – preservation of more distant memories with amnesia for recent events?
 - Is there difficulty learning to use new devices, e.g. computer, mobile phone?
- **Functional ability**
 - Has work performance declined or ability to cook and do domestic tasks?
 - Has responsibility for finances and admin. shifted to the spouse?
 - Does (s)he get easily muddled?
- **Personality and frontal lobe function**
 - Has personality altered?
 - More aggressive/apathetic/lacking initiative?
 - Disinhibition?
 - Change in food preference or religiosity?
- **Language**
 - Difficulty with word finding or remembering names?
- **Visuospatial ability**
 - Does (s)he get lost in familiar places?
 - Difficulty dressing, e.g. putting jacket on the wrong way round?
- **Psychiatric features**
 - Features of depression?
- **Tempo of progression?**
- **Family history of dementia?**
- **Alcohol and drug use?**
- **Medication?**
- **Any other neurological problems, e.g. Parkinsonism, gait disorder, strokes?**

CT scan showing large frontal meningioma presenting with apathy and frontal dementia.

Check for primitive reflexes (frontal release signs) such as grasp, palmo-mental and pout reflexes and perseveration or utilization behaviour with frontal lobe involvement

Test praxis – copying hand gestures and miming tasks – e.g. ‘show me how you brush your teeth’.

Complete neurological examination to look for evidence of, e.g. papilloedema, Parkinsonism, myoclonus, gait disorders is also necessary as is general examination and assessment of mental state.

Investigations (Box 22.30)

Investigations are aimed at identifying treatable causes and helping support a clinical diagnosis of dementia type. For most patients this should include:

Blood tests. FBC, B₁₂, thyroid function, urea and electrolytes, liver function, glucose and ESR.

Brain imaging. CT is adequate to exclude structural lesions, e.g. tumours or hydrocephalus. The superior anatomical resolution of MRI may help identify patterns of regional brain atrophy and so distinguish between different types of degenerative dementia (e.g. hippocampal atrophy in AD vs temporal lobe and frontal atrophy in frontotemporal dementia). Imaging also allows assessment of brain ‘vascular load’.

Detailed neuropsychometric assessment. In some patients, this allows quantification of the relative involvement of different cognitive domains and may be helpful if performed serially over time to assess progression.

Younger patients (<65 years). More intensive investigation is usually necessary. In addition to the tests listed above, EEG, genetic tests (e.g. for Huntington’s, familial AD genes), HIV serology, metabolic tests, and occasionally brain biopsy, may be appropriate.

CSF examination is not routine. However, recently measurement of CSF protein biomarkers has been shown

Box 22.30 Tests in dementia

Blood tests

- Full blood count, ESR, vitamin B₁₂
- Urea and electrolytes
- Glucose
- Liver biochemistry
- Serum calcium
- TSH, T₃, T₄
- HIV serology

Imaging

- CT or MR brain scan

Other – selected patients only

- CSF – including tau and Aβ₄₂ measurement
- Genetic studies, e.g. for AD genes, HD, prion mutations
- EEG
- Brain biopsy

to be useful in distinguishing between different types of dementia, e.g. in AD, CSF and tau is raised and Aβ₄₂ reduced. In CJD and other rapidly progressive dementias protein 14–3–3 is increased.

New imaging modalities. Radionuclide scans using radioactively labelled ligands such as 18F-PIB that bind directly to amyloid allowing amyloid deposition in the brain to be directly imaged have great potential for earlier and more accurate diagnosis of AD. PIB scans are likely to be a part of routine clinical practice in the near future.

Mild cognitive impairment (MCI)

MCI is an intermediate state between normal cognition and dementia. Often mild memory impairment, greater than expected for age but not sufficient to classify as dementia, is the only symptom (‘amnestic MCI’). MCI may be a pre-dementia state with 10–15% of patients per year developing overt Alzheimer’s dementia.

Causes of dementia (Box 22.31)

There are many causes of dementia, by far the commonest being Alzheimer’s disease. Cause varies according to age (Fig. 22.55).

Alzheimer’s disease (AD)

Although technically a definitive diagnosis can only be made by histopathology, in practice the clinical features are sufficiently characteristic that a diagnosis can usually be made with considerable accuracy in life, often supported by diagnostic investigations. The key clinical features are:

- **Memory impairment.** Episodic (autobiographical) memory is affected. There is progressive loss of ability to learn, retain and process new information. There is a characteristic temporal gradient with relative preservation of distant memory and amnesia for more recent events. This is *not* ‘short-term memory loss’ which technically refers to loss of working memory, e.g. digit span, which is preserved in AD.
- **Language** – usually becomes impaired as the disease advances. Difficulty with word finding is characteristic.
- **Apraxia** – impaired ability to carry out skilled motor activities (p. 1068).
- **Agnosia** – failure to recognize objects, e.g. clothing, places or people.
- **Frontal executive function** – impairment of organizing, planning and sequencing.

- **Parietal presentation** with visuospatial difficulties and difficulty with orientation in space and navigation may occur. Parietal lobe involvement is also seen as a later feature in more typical presentations.
- **Posterior cortical atrophy.** The least common presentation of AD with visual disorientation due to initial involvement of the occipital lobes and occipito-parietal regions. Patients have complex visual symptoms that may be difficult to describe; they often say that it is easier to see distant than close up objects. Memory is initially well preserved.

- **Personality.** In contrast to other dementias such as FTD, basic personality and social behaviour remain intact until late AD.
- **Anosognosia.** Lack of insight by the patient into their difficulties is common and they may be reluctant to seek medical attention but be brought by a family member.
- **Tempo.** Onset is insidious and often not noticed by family members initially. Progression is gradual but inexorable over a decade or longer with eventual severe deficits in multiple cognitive domains.
- **Late non-cognitive features.** Myoclonus may develop, sometimes followed by seizures (the cortex is the main site of pathology). Sleep-wake cycle reversal and incontinence may place a great strain on carers. Motor function is usually strikingly preserved so patients are capable of wandering and getting lost. Swallowing may become impaired leading to aspiration pneumonia – often a terminal event.

Box 22.31 Causes of dementia

- Degenerative
 - Alzheimer's disease
 - Dementia with Lewy bodies
 - Frontotemporal dementia
 - Huntington's disease
 - Parkinson's disease
 - Prion diseases, e.g. Creutzfeldt-Jakob
- Vascular
 - Vascular dementia
 - Cerebral vasculitis (rare)
- Metabolic
 - Uraemia
 - Liver failure
- Toxic
 - Alcohol
 - Solvent abuse
 - Heavy metals
- Vitamin deficiency
 - B₁₂ and thiamine
- Traumatic
 - Severe or repeated brain injury
- Intracranial lesions
 - Subdural haematoma
 - Tumours
 - Hydrocephalus
- Infections
 - HIV
 - Neurosyphilis
 - Whipple's disease
 - Tuberculosis
- Endocrine
 - Hypothyroidism
 - Hypoparathyroidism
- Psychiatric
- Pseudodementia

Molecular pathology and aetiology

Although the cause of AD is still not known, a great deal is now understood about the molecular pathology of AD. The pathological hallmarks are the deposition of β -amyloid (A β) in amyloid plaques in the cortex and formation of tau-containing intracellular neurofibrillary tangles. These protein aggregates damage synapses and ultimately lead to neuronal death. Amyloid may also be laid down in cerebral blood vessels leading to amyloid angiopathy.

The amyloid precursor protein (APP) is processed by secretase enzymes to form pathogenic A β_{1-42} monomers which polymerize into amyloid plaques (Fig. 22.56).

A basal forebrain cholinergic deficit occurs and may explain the therapeutic response to cholinesterase inhibitor drugs.

Genetics of AD

A 1st-degree relative with AD confers a doubled lifetime risk of AD. There are rare autosomal dominant monogenic early onset forms of familial AD with high penetrance caused by mutations in specific genes – taken together these only account for 1% of cases of AD.

Amyloid precursor protein (APP). Point mutations in the APP gene can cause AD and the presence of 3 copies of the APP gene on chromosome 21 in Down's syndrome patients is responsible for the high incidence of AD in that condition.

Figure 22.55 Causes of dementia at different ages. (a) <65 years. (b) ≥65 years. (Modified from Kester MI, Scheltens P. Dementia: the bare essentials. Practical Neurology 2009; 9(4):241–251.)

Figure 22.56 Molecular pathogenesis of AD. Processing of the APP molecule by secretase enzymes releases $A\beta_{1-42}$ monomers which are the building block of amyloid plaques. $A\beta$ oligomers may damage synaptic membranes. Mutations in APP or γ -secretase (presenilin-1) cause genetic forms of AD. Disruption of the balance between formation and degradation of $A\beta_{1-42}$ is thought to be important.

Presenilin-1 and 2. Mutations in these genes affect the γ -secretase enzyme function (Fig. 22.56). PS1 mutations account for 50% of monogenic forms of AD. The PS1/2 and APP genes may be sequenced for mutations in selected early onset cases with a family history.

Other genes. The E4 allele of the apolipoprotein E gene confers an increased risk of AD ($\times 2$ – 3 lifetime risk), especially if two copies of the E4 allele are inherited ($\times 6$ – 8 risk). Recently, several other candidate genes have been identified as risk factors for AD in large genome-wide association studies.

Environmental risk factors

Age is the main risk factor for AD as incidence increases exponentially with age. Head trauma and vascular risk factors also increase AD risk. Epidemiological studies show that taking anti-inflammatory drugs over a long period may confer some protection.

Dementia with Lewy bodies (DLB) and Parkinson's disease dementia (PDD)

DLB is characterized by visual hallucinations, fluctuating cognition with variation in attention and alertness, sleep disorders (especially REM sleep behaviour disorder), dysautonomia and Parkinsonism. The visual hallucinations often take the form of people or animals or the sense of a presence ('extracampine hallucinations'). Memory loss may not occur in the early stages. Delusions and transient loss of consciousness occur. Lewy bodies, inclusions containing aggregates of the protein α -synuclein first described in Parkinson's disease are found in the cortex.

In DLB the cognitive features dominate; Parkinsonism may evolve later and is typically mild. In PDD cognitive problems are a late feature, occurring at least 1 year after onset and usually after age 75. Both conditions may respond to cholinesterase inhibitors. Patients with DLB may be very sensitive to neuroleptic drugs with dramatic worsening.

Vascular dementia (multi-infarct dementia)

This common cause of dementia is distinguished from AD by its clinical features and imaging but both may co-exist (mixed dementia). Dementia can be progressive and similar to AD. There is sometimes a history of TIAs or the dementia follows a succession of cerebrovascular events or has a stepwise course. Apraxic gait disorder, pyramidal signs and urinary incontinence are common additional features. Widespread small vessel disease seen on MRI is the typical finding and may produce a variety of cognitive deficits reflecting the site of ischaemic damage.

Frontotemporal dementia (FTD)

A group of neurodegenerative disorders characterized by frontal lobe and temporal lobe atrophy on MRI and at post-mortem. Onset is usually below the age of 65 and there is often a family history. There are three distinct presentations depending on which anatomical region is affected first.

Frontal presentation: personality change, emotional blunting, apathy, disinhibition, carelessness and behavioural change with striking preservation of memory.

Temporal presentations: characterized by progressive impairment of language function. Involvement of the left temporal lobe produces 'semantic dementia', with progressive loss of word-finding ability but fluent speech relatively lacking in meaningful content and difficulty with comprehension of language. The second temporal lobe presentation is progressive non-fluent aphasia due to peri-sylvian atrophy, with loss of verbal fluency and increasingly telegraphic speech.

About 30% of cases are familial, associated with mutations in the tau or progranulin genes; 10% of patients have associated motor neurone disease. There is no cure or specific treatment at present.

Prion diseases including Creutzfeldt-Jakob disease (CJD) (p. 113)

Prion diseases are transmissible neurodegenerative disorders with a long incubation period caused by accumulation of misfolded native prion protein (PrP^c). Misfolding and conformational change in PrP^c is caused either by exposure to the abnormal misfolded isoform of the protein (PrP^{sc}) or mutations in the PrP gene ($PRNP$), leading to toxic accumulation of PrP^{sc} as amyloid in beta-pleated sheets. Neuronal cell damage and 'spongiform' change in the brain result (p. 113), the clinical correlate being a rapidly progressive dementia in most cases.

Creutzfeldt-Jakob disease (CJD) is the commonest prion disease in man, the animal equivalents being bovine spongiform encephalopathy (BSE) in cattle and scrapie in sheep. It may be sporadic, iatrogenic or familial.

Sporadic CJD is the commonest form, occurring over the age of 50, with an incidence of approximately 1 per million. It is thought to be due to spontaneous somatic mutations in the $PRNP$ gene or stochastic conformational change in PrP^c to PrP^{sc} with a subsequent 'domino effect' inducing misfolding in other PrP molecules. A rapidly progressive dementia leads to death within 6 months from onset. Rapidly progressive cognitive decline should always lead to suspicion of CJD. The presence of myoclonus is also a clinical clue (present in 90%). New forms of monoclonal antibody treatment are being studied.

Iatrogenic CJD is transmitted from neurosurgical instruments (prions are resistant to sterilization), transplant material (e.g. corneal grafts) and cadaveric pituitary derived growth hormone taken from patients with CJD or presymptomatic CJD. Iatrogenic CJD has a long incubation period of several years.

Familial CJD (rare) is associated with PRNP gene mutations. Other clinical phenotypes such as *familial fatal insomnia* also occur.

Variant CJD (vCJD) was first seen in the UK in 1995. vCJD patients are younger than sporadic cases with a mean age of 29. Early symptoms are neuropsychiatric, followed by ataxia and dementia with myoclonus or chorea. The diagnosis can be confirmed by tonsillar biopsy but very recently a sensitive blood test has been developed. vCJD has a longer course than sporadic CJD – up to several years. vCJD and BSE are caused by the same prion strain, giving rise to speculation that transmission from animal to human food chain occurred, i.e. infection from BSE-infected cattle to humans (p. 113). Transmission via blood transfusion may also occur. Most patients with vCJD and sporadic CJD have a specific polymorphism at codon 129 of the PRNP gene that leads to susceptibility.

Other dementias

Other neurodegenerative disorders may include dementia as one of their clinical manifestations, e.g. corticobasal degeneration (CBD), progressive supranuclear palsy (PSP), and dementia may be a feature of a number of genetic and metabolic disorders, e.g. Huntington's disease (p. 1121) and the leucodystrophies.

Treatment

It is rare that a treatable cause for dementia is found, for example hypothyroidism. Management is supportive, to preserve dignity and to provide care for as long as possible in the familiar home environment. The burden of illness falls frequently on relatives. Dementia clinical nurse specialists form a central part of the multidisciplinary team.

General measures. Some evidence suggests that participation in cognitively demanding activities in later life may protect against or delay the onset of dementia. High-dose B vitamins may possibly slow conversion from MCI to AD.

Cognitive enhancers. They have a modest symptomatic benefit in AD, equivalent to an increase in 1–2 points on the MMSE. They are not disease modifying, so do not slow or prevent progression. Whilst there is dispute about the place for these drugs – all are costly – they contribute in some cases to patients being able to prolong independence and remain at home for longer than might otherwise be the case.

Cholinesterase inhibitors (donepezil, rivastigmine and galantamine) increase brain acetylcholine levels by inhibiting CNS acetylcholinesterase. Cholinesterase inhibitors are also effective in DLB and Parkinson's dementia but not in FTD or vascular dementia.

Memantine is an *NMDA receptor antagonist*. It is used in moderate or severe AD or where cholinesterase inhibitors are not tolerated. There is some evidence that combination of Memantine and cholinesterase inhibitors is better than either used alone.

Psychiatric and behavioural problems. Depression is common in dementia and may be difficult to distinguish from dementia symptoms such as apathy and worsening cognitive function. A trial of an antidepressant is appropriate where depression is suspected. Distinguishing depressive pseudodementia from organic dementia can be difficult but is crucial. Behavioural disturbance (e.g. due to agitation or delusions) and hallucinations may occur in late stage disease. Use of antipsychotic medications is associated with significantly increased stroke risk in patients with dementia and should only be used as a last resort.

Drugs in development. The greatest need is for disease modifying therapies that halt or slow progression in early

stage disease. Potential treatments in development include anti-amyloid therapies such as monoclonal antibodies directed against A β and inhibitors of secretase enzymes that process APP into A β fragments.

Financial and legal issues. Patients may want to set up a Lasting Power of Attorney (if they retain mental capacity to do so in legal terms) to allow a spouse or relative to deal with their financial affairs on their behalf when they lose the capacity to do so. Patients and carers may be entitled to state financial benefits.

Driving. After a diagnosis of dementia patients in the UK have a duty to inform the DVLA licensing authority who may request a driving safety assessment.

Motor neurone disease (MND)

Motor neurone disease is a devastating condition causing progressive weakness and eventually death, usually as a result of respiratory failure or aspiration. It is relatively uncommon with an annual incidence of 2/100 000. Presentation is usually between ages 50 and 75. Below age 70 men are affected more often than women. ALS (amyotrophic lateral sclerosis) is the term more commonly used for MND in some countries.

Pathogenesis

MND predominantly affects upper and lower motor neurones in the spinal cord, cranial nerve motor nuclei and cortex. However, other neuronal systems may also be affected – 5% of patients also develop frontotemporal dementia (p. 1087) and up to 40% have some measurable frontal lobe cognitive impairment. MND is usually sporadic and of unknown cause with no known environmental risk factors. Ubiquitinated cytoplasmic inclusions containing the RNA processing proteins TDP-43 and FUS are the pathological hallmarks found in axons, indicating that protein aggregation may be involved in pathogenesis as with other neurodegenerative disorders. Oxidative neuronal damage and glutamate mediated excitotoxicity have also been implicated in pathogenesis.

5–10% of cases of MND are familial and mutations in the free radical scavenging enzyme superoxide dismutase (SOD-1) and in a number of other genes including TDP-43 and FUS have been identified. A hexanucleotide GGGGCC repeat expansion in the C9ORF72 gene on chromosome 9 accounts for a significant proportion of familial cases of MND-FTD overlap.

Clinical features

Four main clinical patterns are seen. These different presentations usually merge as MND progresses. The sensory system is not involved so sensory symptoms such as numbness, tingling and pain do not occur.

- **Amyotrophic lateral sclerosis (ALS).** The classic presentation with simultaneous involvement of upper and lower motor neurones, usually in one limb, spreading gradually to other limbs and trunk muscles. The typical picture is of progressive focal muscle weakness and wasting (e.g. in one hand) with muscle fasciculations due to spontaneous firing of abnormally large motor units formed by surviving axons branching to innervate muscle fibres that have lost their nerve supply. Cramps are a common but nonspecific symptom. Examination often reveals upper motor neurone signs such as brisk reflexes (a brisk reflex in a wasted muscle is a classic sign), extensor plantar responses and spasticity. Sometimes an asymmetric spastic paraparesis is the presenting feature with lower

FURTHER READING

Renton AE, Majounie E, Waite A et al. A hexanucleotide repeat expansion in C9ORF72 is the cause of chromosome 9p21-linked ALS-FTD. *Neuron* 2011; 72:257–268.

motor neurone features developing months later. Relentless progression of signs and symptoms over months allows a diagnosis that may initially be suspected to be confirmed.

- **Progressive muscular atrophy.** A pure lower motor neurone presentation with weakness, muscle wasting and fasciculations, usually starting in one limb and gradually spreading to involve other adjacent spinal segments.
- **Progressive bulbar and pseudobulbar palsy** (20%). The lower cranial nerve nuclei and their supranuclear connections are initially involved. Dysarthria, dysphagia, nasal regurgitation of fluids and choking are the presenting symptoms. A fasciculating tongue with slow, stiff tongue movements is the classic finding in a mixed bulbar palsy. Emotional incontinence with pathological laughter and crying may occur in pseudobulbar palsy.
- **Primary lateral sclerosis** (rare 1–2%). The least common form of MND confined to upper motor neurones, causing a slowly progressive tetraparesis and pseudobulbar palsy.

Diagnosis

Diagnosis is largely clinical. There are no diagnostic tests but investigations allow exclusion of other disorders and may confirm subclinical involvement of muscle groups, e.g. paraspinal muscles. Denervation of muscles due to degeneration of lower motor neurones is confirmed by EMG.

Cervical spondylosis causing radiculopathy with myelopathy (upper and lower motor neurone signs), can cause diagnostic difficulty. Motor neuropathies such as multifocal motor neuropathy can also appear like motor neurone disease (see p. 1146).

Prognosis and treatment

Survival for more than 3 years is unusual, although there are rare MND cases who survive for a decade or longer.

No treatment has been shown to influence outcome substantially. Riluzole, a sodium-channel blocker that inhibits glutamate release, slows progression slightly, increasing life expectancy by 3–4 months on average. Non-invasive ventilatory support and feeding via a gastrostomy help prolong survival. Patients should be supported by a specialist multi-disciplinary team with access to palliative care and a clinical nurse specialist.

CONGENITAL DISORDERS

Cerebral palsy

Cerebral palsy (CP) is an umbrella term encompassing disparate disorders apparent at birth or in childhood characterized by non-progressive motor deficits. It is the commonest form of physical disability in childhood and most affected children survive into adulthood. A variety of intrauterine and neonatal cerebral insults may cause CP including prematurity and its complications, hypoxia, intrauterine infections and kernicterus. In many cases, no specific cause can be identified.

Clinical features

Failure to achieve normal milestones is usually the earliest feature. Specific motor syndromes become apparent later in childhood or, rarely, in adult life.

- **Spastic diplegia** – lower limb spasticity, with scissoring of gait
- **Athetoid cerebral palsy** (p. 1121)
- **Infantile hemiparesis.** Hemiparesis may be noted at birth or later. One hemisphere is hypotrophic and the contralateral, hemiparetic limbs small (hemiatrophy)
- **Ataxic and dystonic CP**
- **Co-morbidity** – particularly epilepsy and learning difficulty are common and at least as disabling as the motor deficit.

Dysraphism

Failure of normal fusion of the fetal neural tube leads to a group of congenital anomalies. Folate deficiency during pregnancy is contributory: supplements should always be given (p. 211). Antiepileptic drugs, e.g. valproate, are also implicated (p. 1116). If there is access from the skin, e.g. a sinus connecting to the subarachnoid space, bacterial meningitis may follow.

- **Meningoencephalocele.** Brain and meninges extrude through a midline skull defect – protrusion can be minor or massive.
- **Spina bifida** is failure of lumbosacral neural tube fusion. Several varieties occur.
- **Spina bifida occulta** is isolated failure of vertebral arch fusion (usually lumbar), often seen incidentally on X-rays (3% of the population). A dimple or a tuft of hair may overlie the anomaly; clinical abnormalities are unusual.
- **Meningomyelocele with spina bifida.**

Meningomyelocele consists of elements of spinal cord and lumbosacral roots within a meningeal sac. This herniates through a vertebral defect. In severe cases both lower limbs and sphincters are paralysed. Meningocele is a meningeal defect alone. The defect should be closed in the first 24 h after birth.

NEUROGENETIC DISORDERS

Of the 20–30 000 human genes approximately 80% are expressed in the brain. It is therefore not surprising that of the 5000 or so Mendelian disorders of man, a high proportion are neurological disorders. Several hundred neurological disease genes have been identified and molecular genetic testing is now part of the neurological diagnostic process. Many of these disorders are largely covered in individual disease sections of this chapter.

Neurocutaneous syndromes

Neurofibromatosis type 1 (von Recklinghausen's disease, NF-1)

One of the commonest neurogenetic disorders with a prevalence 1 in 3000. Inheritance is autosomal dominant but 50% of cases are due to new mutations with no family history. The protein is called neurofibromin1. NF-1 is characterized by multiple skin neurofibromas and pigmentation (café-au-lait patches p. 1219, axillary freckling and iris Lisch nodules). The neurofibromas arise from the neurilemmal sheath.

Skin neurofibromas present as soft subcutaneous, sometimes pedunculated, lumps (p. 1219). They increase in number throughout life. Plexiform neurofibromas may develop on major nerves and proximal nerve roots, sometimes involving the spinal cord. Treatment is surgical removal if pressure

FURTHER READING

Kiernan MC et al. Amyotrophic lateral sclerosis. *Lancet* 2011; 377:942–955.

symptoms develop. Associated features include: learning difficulties, malignant transformation of neurofibromas, bone abnormalities including scoliosis and fibrous dysplasia.

Neurofibromatosis type 2 (NF-2)

NF-2 is much less common than NF-1. It is also autosomal dominant; the gene product Merlin or Schwannomin is a cytoskeletal protein. Many neural tumours occur:

- Acoustic neuromas (usually bilateral) in 90%
- Meningiomas
- Gliomas (including optic nerve glioma)
- Cutaneous neurofibromas (30%).

Tuberous sclerosis (epiloia)

Features of this rare multi-system autosomal dominant condition include adenoma sebaceum, renal tumours and glial overgrowth in the brain (cortical tubers and sub-ependymal nodules). Epilepsy (70%) and learning difficulties (50%) are common complications.

Von Hippel–Lindau disease

This rare condition is dominantly inherited. Cerebellar, spinal and retinal haemangioblastomas develop and can be surgically removed. Tumours – renal cell carcinoma and phaeochromocytomas – may also occur. Polycythaemia sometimes develops.

Spinocerebellar ataxias (SCAs)

A wide variety of genetic disorders cause cerebellar ataxia as the sole or predominant clinical feature. Many are due to trinucleotide repeat insertions.

Early onset ataxia (<20 years of age)

Most early childhood onset inherited ataxias are autosomal recessive. Friedreich's ataxia (FRDA) is by far the commonest, caused by a GAA trinucleotide repeat expansion in the frataxin gene (involved in mitochondrial iron metabolism). Onset is in early teens with progressive difficulty in walking due to cerebellar ataxia and sensory neuropathy. Associated features include: scoliosis, cardiomyopathy, optic atrophy, areflexia and diabetes.

Ataxia telangiectasia and ataxia with vitamin E deficiency are other rarer forms of autosomal recessive inherited ataxia.

Late onset ataxia (>20 years of age)

Adult onset inherited ataxias are usually dominantly inherited and there are some 30 different genetic forms, many caused by CAG trinucleotide repeats. There are three main categories of autosomal dominant cerebellar ataxia (ADCA):

ADCA-1: progressive ataxia with variable additional features including peripheral neuropathy, pyramidal and extrapyramidal signs, and cognitive impairment. Caused by mutations in loci SCA1–3.

ADCA-2: progressive ataxia with macular dystrophy. Rare. SCA7 gene.

ADCA-3: late adult life onset 'pure' ataxia. SCA6 gene in 50%. Non-genetic phenocopies must be excluded.

PARANEOPLASTIC SYNDROMES

Neurological disease may accompany malignancy in the absence of metastases. These paraneoplastic syndromes

are associated with anti-neuronal antibodies, believed to be involved in generation of signs and symptoms. Numerous anti-neuronal antibodies have been described.

Clinical pictures include:

- Sensorimotor neuropathy (p. 1146)
- Lambert–Eaton myasthenic-myopathic syndrome (LEMS, p. 1152) and myasthenia gravis with thymoma
- Motor neurone disease variants (p. 1152)
- Spastic paraparesis (p. 1136)
- Cerebellar syndrome (p. 1084)
- Limbic encephalitis (p. 1129)
- Paraneoplastic stiff person syndrome (see p. 1153).

The neurological syndrome usually precedes evidence of the neoplasm – often a small-cell bronchial carcinoma, breast or ovarian cancer. Diagnosis is based on the clinical pattern and antibody profile. Neuroimaging is typically normal. Treatment is often unsatisfactory.

PERIPHERAL NERVE DISEASE

Mechanisms of damage to peripheral nerves

Peripheral nerves consist of two principal cellular structures – the nerve nucleus with its axon and the myelin sheath, which is produced by Schwann cells between each node of Ranvier (Fig. 22.1). Blood supply is via vasa nervorum. Several mechanisms, some co-existing, cause nerve damage.

Demyelination

Schwann cell damage leads to myelin sheath disruption. This causes marked slowing of conduction, seen for example in Guillain–Barré syndrome and many genetic neuropathies.

Axonal degeneration

Axon damage leads to the nerve fibre dying back from the periphery. Conduction velocity initially remains normal (*cf.* demyelination) because axonal continuity is maintained in surviving fibres. Axonal degeneration occurs typically in toxic neuropathies. A wide range of toxic and metabolic disorders damage peripheral nerves as their long axons (requiring cellular transport of proteins from cell body to nerve terminals) make them uniquely vulnerable. This explains the concept of length dependent neuropathy with the longest, most vulnerable axons (to the toes) being affected first.

Compression

Focal demyelination at the point of compression causes disruption of conduction. This occurs typically in entrapment neuropathies, e.g. carpal tunnel syndrome (p. 1144).

Infarction

Microinfarction of vasa nervorum occurs in diabetes and arteritis, e.g. polyarteritis nodosa, Churg–Strauss syndrome (p. 847). Wallerian degeneration occurs distal to the infarct.

Infiltration

Infiltration of peripheral nerves by inflammatory cells occurs in leprosy and granulomas, e.g. sarcoid, and by neoplastic cells.

Nerve regeneration

Regeneration occurs either by remyelination – Schwann cells produce new myelin sheaths around an axon – or

England JD, Ashbury AK. Peripheral neuropathy. *Lancet* 2004; 363:2151–2161.

Figure 22.57 Peripheral neuropathies. The type of neuropathy (axonal or demyelinating) can be assessed by electrical nerve studies (p. 1090).

by axonal growth down the nerve sheath with sprouting from the axonal stump. Axonal growth takes place at up to 1 mm/day.

Types of peripheral nerve disease

(Fig. 22.57)

- **Neuropathy** simply means a pathological process affecting a peripheral nerve or nerves.
- **Mononeuropathy** means a process affecting a single nerve.
- **Mononeuritis multiplex**, several individual nerves are affected.
- **Polyneuropathy** describes diffuse, symmetrical disease, usually commencing peripherally. The course may be acute, chronic, static, progressive, relapsing or towards recovery. Polyneuropathies are motor, sensory, sensorimotor and autonomic. They are classified broadly into demyelinating and axonal types, depending upon which principal pathological process predominates. It is often impossible to separate these clinically. Many systemic diseases cause neuropathies. Widespread loss of tendon reflexes is typical, with distal weakness and distal sensory loss.
- **Radiculopathy** means disease affecting nerve roots and *plexopathy*, the brachial or lumbosacral plexus.

Diagnosis is made by clinical pattern, nerve conduction/EMG, nerve biopsy, usually sural or radial, and identification of systemic or genetic disease.

Mononeuropathies

Peripheral nerve compression and entrapment (Table 22.24)

Nerves are vulnerable to mechanical compression at a few key sites, e.g. the common peroneal nerve at the head of the fibula, or the ulnar nerve at the elbow. Entrapment develops in relatively tight anatomical passages, e.g. the carpal tunnel. Focal demyelination predominates at the compression site, and some distal axonal degeneration occurs.

These neuropathies are recognized largely by clinical features. Diagnosis is confirmed by nerve conduction studies.

The commonest are mentioned here. All are seen more frequently in people with diabetes.

Carpal tunnel syndrome (CTS)

This common mononeuropathy, median nerve entrapment at the wrist, is usually known as carpal tunnel syndrome (CTS) (p. 502). CTS is typically not associated with any underlying disease. CTS is, however, seen in:

- Hypothyroidism
- Pregnancy (3rd trimester)

Table 22.24 Nerve compression and entrapment

Nerve	Entrapment/compression site
Median	Carpal tunnel (wrist)
Ulnar	Cubital tunnel (elbow)
Radial	Spiral groove (of humerus)
Posterior interosseous	Supinator muscle (forearm)
Lateral cutaneous of thigh	Inguinal ligament
Common peroneal	Neck of fibula
Posterior tibial	Tarsal tunnel (flexor retinaculum – foot)

- Rheumatoid disease
- Acromegaly
- Amyloid including in dialysis patients.

There is nocturnal painful tingling in the hand and/or forearm – usually poorly localized and *not* confined to the anatomical sensory territory of the nerve. Weakness and wasting of thenar muscles is a late feature. *Tinel's sign* is often present and *Phalen's test* positive. Tinel's is elicited by tapping the flexor aspect of the wrist: this causes tingling and pain. In Phalen's, symptoms are reproduced on passive maximal wrist flexion.

A wrist splint at night or a local steroid injection (p. 502) in the wrist gives relief in mild cases. In pregnancy CTS is often self-limiting as fluid retention subsides postpartum. Surgical decompression of the carpal tunnel is the definitive treatment.

Ulnar nerve compression

The nerve is compressed in the cubital tunnel at the elbow. This follows prolonged or recurrent pressure and elbow fracture ('tardy ulnar palsy' as onset is very delayed).

There is clawing of the hand, wasting of interossei and hypothenar muscles, and weakness of interossei and medial two lumbricals – with sensory loss in the little finger and splitting the ring finger. Decompression and transposition of the nerve at the elbow is sometimes helpful but often disappointing.

The deep, solely motor branch of the ulnar nerve can be damaged in the palm by repeated trauma, e.g. from a crutch, screwdriver handle, or cycle handlebars.

Radial nerve compression

The radial nerve is compressed acutely against the humerus, e.g. when the arm is draped over a hard chair for several hours, known as Saturday night palsy. Wrist drop and weakness of brachioradialis and finger extension follow. Recovery is usual, though not invariable, within 1–3 months. Posterior interosseous nerve compression in the forearm also leads to wrist drop, without weakness of brachioradialis.

Lateral cutaneous nerve of the thigh compression

This is also known as meralgia paraesthetica and is described on page 506.

Common peroneal nerve palsy

The common peroneal nerve is compressed against the head of the fibula following prolonged squatting, yoga, pressure from a cast, prolonged bed rest or coma, or for no apparent reason. There is foot drop and weakness of ankle eversion. The ankle jerk (S1) is preserved. A patch of numbness develops on the anterolateral border of the dorsum of the foot and/or lateral calf. Confusion with an L5 motor radiculopathy may

occur. Recovery is usual, though not invariable, within several months.

Hereditary neuropathy with pressure palsies (HNPP)

The genetic converse of CMT 1A (p. 1148), this dominantly inherited disorder is due to deletion of the PMP-22 gene. Patients are susceptible to pressure palsies after minor compression episodes; even the brachial plexus may be involved. There is also a mild background neuropathy that gradually develops. Genetic testing can be performed.

Mononeuritis multiplex

This occurs in:

- Diabetes mellitus
- Leprosy
- Vasculitis including Churg–Strauss
- Amyloidosis
- Malignancy
- Neurofibromatosis
- HIV and hepatitis C infection
- Multifocal motor neuropathy with conduction block.

Several nerves become affected sequentially or simultaneously, e.g. ulnar, median, radial and lateral popliteal nerves. When multifocal neuropathy is symmetrical, there is difficulty distinguishing it from polyneuropathy.

Polyneuropathies (peripheral neuropathy)

Many diseases cause polyneuropathy. The diagnosis should not stop with identification of the polyneuropathy, but involve a full diagnostic work-up to identify the underlying cause (Box 22.32). However, despite thorough investigation the aetiology remains unknown in 50% of cases.

Clinical features. Duration, distribution and pattern of the different types of polyneuropathy vary considerably

Neurophysiological features. Nerve conduction studies allow separation into axonal and demyelinating forms.

Diagnostic investigations (in addition to neurophysiology). A stepped approach can be taken – Table 22.25.

Immune-mediated neuropathies

Guillain–Barré syndrome (GBS)

Clinical features

Also called acute inflammatory demyelinating polyradiculoneuropathy (AIDP). GBS is the most common acute polyneuropathy (3/100 000 per year); it is usually demyelinating or occasionally axonal and has an immune-mediated, often post-infectious, basis. GBS is monophasic – it does not recur. The clinical spectrum of GBS extends to an acute motor axonal neuropathy (AMAN) and the Miller–Fisher syndrome – a rare proximal form causing ocular muscle palsies and ataxia.

Paralysis follows 1–3 weeks after an infection that is often trivial and seldom identified. *Campylobacter jejuni* and

Table 22.25 Investigations in peripheral neuropathy

Initial investigations	
Blood tests	FBC, ESR, B ₁₂ Renal, liver, Thyroid function Glucose Protein electrophoresis, immunoglobulins/ immunofixation ANA
Chest X-ray	
Urine	Bence Jones proteins, casts
Selected patients	
Nerve biopsy	
Blood tests	Anti-ganglioside antibodies Anti-MAG antibodies HIV, Lyme, Hep C, Cryoglobulins, vasculitis screen Anti-Ro and La Porphyrins Genetic tests (e.g. Friedreich's ataxia) ACE Serum free light chains Anti-neuronal antibodies
Search for malignancy	
CSF analysis for protein	
Labial salivary gland biopsy for Sjögren's	
Slit skin smear for leprosy	
Nerve conduction studies are performed to differentiate axonal from demyelinating forms	

cytomegalovirus infections are well-recognized causes of severe GBS. Infecting organisms induce antibody responses against peripheral nerves. Molecular mimicry, i.e. sharing of homologous epitopes between microorganism liposaccharides and nerve gangliosides (e.g. GM1), is the possible mechanism.

The patient complains of weakness of distal limb muscles and/or distal numbness. Low back pain is a frequent early feature. The weakness and sensory loss progresses proximally, over several days to 6 weeks. Predominant proximal muscle involvement may occur and rarely pure sensory forms. Loss of tendon reflexes is almost invariable. In mild cases, there is mild disability before spontaneous recovery begins, but in some 20% respiratory and facial muscles become weak, sometimes progressing to complete paralysis. Autonomic features sometimes develop.

Diagnosis

This is established on clinical grounds and confirmed by nerve conduction studies; these show slowing of conduction in the common demyelinating form, prolonged distal motor latency and/or conduction block. CSF protein is often raised to 1–3 g/L; cell count and glucose level remain normal.

In the Miller–Fisher syndrome antibodies against GQ1b (ganglioside) have a sensitivity of 90%.

Differential diagnosis includes other acute paralytic illnesses, e.g. botulism, cord compression, muscle disease and myasthenia.

Course and management

Paralysis may progress rapidly (hours/days) to require ventilatory support. It is essential that ventilation (vital capacity) is monitored repeatedly to recognize emerging respiratory muscle weakness. LMW heparin (p. 429) and compression stockings should be used to reduce the risk of venous thrombosis.

Box 22.32 Varieties of polyneuropathy

- Guillain–Barré syndrome
- Chronic inflammatory demyelinating polyradiculoneuropathy
- Idiopathic sensorimotor neuropathy
- Metabolic, toxic and vitamin deficiency neuropathies (see Box 22.33)

Immunoglobulin given intravenously within the first 2 weeks reduces duration and severity of paralysis. Patients should be screened for IgA deficiency before immunoglobulin is given – severe allergic reactions due to IgG antibodies may occur when congenital IgA deficiency is present. Plasma exchange is an alternative. Prolonged ventilation may be necessary. Improvement towards independent mobility is gradual over many months or even years but may be incomplete. 5–8% either die and 30% are left disabled.

Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP)

CIDP develops over months, causing progressive or relapsing proximal and distal limb weakness with sensory loss. Variants such as the sensory ataxic form and multifocal motor neuropathy occur. In some cases cranial nerves may be involved.

There is no single diagnostic test but CSF protein is raised and patchy demyelination is usually seen on nerve conduction studies. Some cases are associated with a serum paraprotein. Nerve biopsy is sometimes required. CIDP responds to long-term immunosuppression with steroids or to i.v. immunoglobulin in acute stages.

Multifocal motor neuropathy with conduction block (MMNCB)

A distal immune-mediated focal demyelinating motor neuropathy (often asymmetrical and predominantly in the hands) develops gradually over months with profuse fasciculation, hence confusion with motor neurone disease (in this chapter). Conduction block and denervation are seen electrically. Antibodies to the ganglioside GM₁ are found in over 50% of cases; this is nonspecific – antibodies are sometimes seen in other neuropathies, e.g. Guillain-Barré syndrome.

Treatment is usually with regular intravenous immunoglobulin infusions that produce immediate improvement. Steroids may cause worsening and should be avoided.

Paraproteinaemic neuropathies

Up to 70% of patients with a serum paraprotein have a neuropathy and some 10% of patients with no other identifiable cause for their neuropathy have a paraprotein. Most are associated with MGUS (p. 471) but they are also seen in myeloma (see neuropathy in cancer, p. 1148). The antibody may be pathogenic for the neuropathy (e.g. antiMAG) or coincidental in some cases.

IgM paraproteins: usually a demyelinating neuropathy. Often directed against myelin associated glycoprotein (anti-MAG). The anti-MAG phenotype is a slowly progressive distal neuropathy with ataxia and prominent tremor.

POEMS syndrome: Polyneuropathy (demyelinating), Organomegaly (hepatomegaly 50%), Endocrinopathy (reduced testosterone usually), an **M** (para)protein band, and Skin changes. Probably caused by vascular endothelial growth factor (VEGF) release from a plasmacytoma. Treatment is of the plasmacytoma/plasma cell dyscrasia.

Chronic sensorimotor neuropathy: no cause found

This situation is common – progressive symmetrical numbness and tingling occurs in hands and feet, spreading proximally in a glove and stocking distribution. Distal weakness also ascends. Tendon reflexes are lost. Symptoms may progress, remain static or occasionally remit. Autonomic features are sometimes seen.

Box 22.33 Metabolic, toxic and vitamin deficiency neuropathies

Metabolic

- Diabetes mellitus
- Uraemia
- Hepatic disease
- Thyroid disease
- Porphyrria
- Amyloid disease
- Malignancy
- Refsum's disease
- Critical illness

Toxic

- Drugs (Table 22.26)
- Alcohol
- Industrial toxins, e.g. lead, organophosphates

Vitamin deficiency

- B₁ (thiamin)
- B₆ (pyridoxine)
- Nicotinic acid
- B₁₂
- Drug-related neuropathies (Table 22.26)
- Hereditary sensorimotor neuropathies, e.g. Charcot-Marie-Tooth
- Other polyneuropathies:
 - Neuropathy in cancer
 - Neuropathies in systemic diseases
 - Autonomic neuropathy
 - HIV-associated neuropathy
 - Critical illness neuropathy

Nerve conduction studies usually show axonal degeneration. Nerve biopsy helps to classify some cases, for example diagnosing CIDP, or unsuspected vasculitis.

Metabolic, toxic and vitamin deficiency neuropathies

Causes of the most common neuropathies are shown in Box 22.33.

Metabolic neuropathies

Diabetes mellitus. The commonest cause of neuropathy in developed countries; 50% of patients with diabetes have neuropathy after 25 years – good glycaemic control is protective from this microvascular complication of diabetes. Several varieties of neuropathy occur (p. 1026):

- **Distal symmetrical sensory neuropathy:** usually mild and asymptomatic. Related to diabetes duration and glycaemic control
- **Acute painful sensory neuropathy** (reversible with improved glycaemic control)
- **Mononeuropathy and multiple mononeuropathy** (mononeuritis multiplex):
 - cranial nerve lesions
 - individual mononeuropathies (e.g. carpal tunnel syndrome) or mononeuritis multiplex
- **Diabetic amyotrophy:** a reversible vasculitic plexopathy or femoral neuropathy
- **Autonomic neuropathy.**

Uraemia. Progressive sensorimotor neuropathy develops in chronic uraemia. Response to dialysis is variable; the neuropathy usually improves after transplantation.

Thyroid disease. A mild chronic sensorimotor neuropathy is sometimes seen in both hyperthyroidism and hypothyroidism. Myopathy also occurs in hyperthyroidism (p. 964).

Porphyria. In acute intermittent porphyria (p. 1043) there are episodes of a severe, mainly proximal neuropathy in the limbs, sometimes with abdominal pain, confusion and coma. Alcohol, barbiturates and intercurrent infection can precipitate attacks.

Amyloidosis. Polyneuropathy or multifocal neuropathy develops (p. 1042).

Toxic neuropathies

Alcohol

Polyneuropathy, mainly in the lower limbs, occurs with chronic alcohol use. It is a common cause of neuropathy. A myopathy may accompany it. For other neurological consequences of alcohol, see Box 22.34.

Drugs and industrial toxins

Many drugs (Table 22.26) and a wide variety of industrial toxins cause polyneuropathy. Toxins include:

- Lead – motor neuropathy
- Acrylamide (plastics industry), trichlorethylene, hexane, fat-soluble hydrocarbons, e.g. glue-sniffing, page 1184
- Arsenic, thallium and heavy metals.

Box 22.34 Neurological effects of ethyl alcohol

- Acute intoxication:
 - Disturbance of balance, gait and speech
 - Coma
 - Head injury and sequelae
- Alcohol withdrawal:
 - Morning shakes
 - Tremor
 - Delirium tremens
- Thiamin deficiency:
 - Polyneuropathy
 - Wernicke–Korsakoff
- Epilepsy
- Acute intoxication
- Alcohol withdrawal
- Hypoglycaemia
- Cerebellar degeneration
- Cerebral infarction
- Cerebral atrophy, dementia
- Central pontine myelinolysis
 - Marchiafava–Bignami syndrome (corpus callosum degeneration, rare)

Table 22.26 Drug-related neuropathies

Drug	Neuropathy	Mode/site of action
Phenytoin	M	A
Chloramphenicol	S, M	A
Metronidazole	S, S/M	A
Isoniazid	S, S/M	A
Dapsone	M	A
Antiretroviral drugs	S > M	A
Nitrofurantoin	S/M	A
Vincristine	S > M	A
Paclitaxel	S > M	A
Disulfiram	S, M	A
Cisplatin	S	A
Amiodarone	S, M	D, A
Chloroquine	S, M	A, D
Suramin	M > S	D, A

A, axonal; D, demyelinating; M, motor; S, sensory.

Vitamin deficiencies

Vitamin deficiencies cause nervous system damage that is potentially reversible if treated early, and progressive if not. Deficiencies, often of multiple vitamins, develop in malnutrition.

Thiamin (vitamin B₁)

Dietary deficiency causes *beriberi* (p. 209). Its principal features are polyneuropathy and cardiac failure. Thiamine deficiency also leads to Wernicke's encephalopathy and Korsakoff psychosis. Alcohol is the commonest cause in western countries and, rarely, anorexia nervosa or vomiting of pregnancy.

Wernicke–Korsakoff syndrome. This thiamin-responsive encephalopathy is due to damage in the brainstem and its connections. It consists of:

- **Eye signs** – nystagmus, bilateral lateral rectus palsies, conjugate gaze palsies
- **Ataxia** – broad-based gait, cerebellar signs and vestibular paralysis
- **Cognitive change** – acutely stupor and coma, later an amnesic syndrome with confabulation.

Wernicke–Korsakoff syndrome is underdiagnosed. Thiamine should be given parenterally if the diagnosis is a possibility. Untreated Wernicke–Korsakoff syndrome commonly leads to an irreversible amnesic state. Erythrocyte transketolase activity is reduced but the test is rarely available.

Pyridoxine (vitamin B₆)

Deficiency causes a mainly sensory neuropathy. In practical terms this is seen as limb numbness developing during anti-TB therapy in slow isoniazid acetylators (p. 913). Prophylactic pyridoxine 10 mg daily is given with isoniazid.

Vitamin B₁₂ (cobalamin)

Deficiency causes damage to the spinal cord, peripheral nerves and brain.

Subacute combined degeneration of the cord (SACD).

Combined cord and peripheral nerve damage is a sequel of Addisonian pernicious anaemia and rarely other causes of vitamin B₁₂ deficiency (p. 382). Initially there is numbness and tingling of fingers and toes, distal sensory loss, particularly posterior column, absent ankle jerks and, with cord involvement, exaggerated knee jerks and extensor plantars. Optic atrophy and retinal haemorrhage may occur. In later stages sphincter disturbance, severe generalized weakness and dementia develop. Exceptionally, dementia develops in the early stages.

Macrocytosis with megaloblastic marrow is usual though not invariable in SACD. Parenteral B₁₂ reverses nerve damage but has little effect on the cord and brain. Without treatment, SACD is fatal within 5 years. Copper deficiency is a very rare cause of a similar picture.

Genetic neuropathies

Inherited neuropathy may occur as 'pure' neuropathy disorders (e.g. CMT) or as part of a neurological multi-system disorder, e.g. SCAs (p. 1143).

Charcot–Marie–Tooth (CMT) disease

CMT disease is a complex group of heterogeneous motor and sensory neuropathies with multiple causative genes. Distal limb wasting and weakness typically progress slowly over many years, mostly in the legs, with variable loss of sensation and reflexes. In advanced disease severe foot drop results but patients usually remain ambulant. Mild

FURTHER READING

Triggs WJ, Brown RH, Menkes DL. Case records of the Massachusetts General Hospital. Case 18-2006. A 57-year-old woman with numbness and weakness of the feet and legs. *N Engl J Med* 2006; 354:2584–2592.

cases have pes cavus and toe clawing that can pass unnoticed.

- **HSMN Ia (CMT 1A)** – the commonest (70% of CMT; 1:2500 births), autosomal dominant demyelinating neuropathy caused by duplication (or point mutation) of a 1.5 megabase portion p11.2 of chromosome 17 encompassing the peripheral myelin protein 22 gene (*PMP-22*, 17p11.2).
- **HSMN Ib (CMT 1B)** – the second commonest, an autosomal dominant demyelinating neuropathy due to mutations in the myelin protein zero gene (*MPZ*) on chromosome 1 (1q22).
- **HSMN II (CMT 2)** – rare axonal polyneuropathies also caused by *MFN2* or *KIF1B* on chromosome 1p36 and other mutations. There is prominent sensory involvement with pain and paraesthesias.
- **Distal spinal muscular atrophy** – a rare cause of CMT phenotype.
- **CMT with optic atrophy**, deafness, retinitis pigmentosa and spastic paraparesis.
- **CMTX** is an X-linked dominant HSMN on chromosome Xq13.1. The gene product is a gap junction B1 protein (*GJB1*) or connexin 32 (p. 24).

HSMN III

HSMN III is a rare childhood demyelinating sensory neuropathy (Déjérine-Sottas disease) leading to severe incapacity during adolescence. Nerve roots become hypertrophied. CSF protein is greatly elevated to ≥ 10 g/L. Point mutations either of *PMP-22* gene or of *P0* can generate this phenotype.

Other polyneuropathies**Neuropathy in cancer**

Polyneuropathy is seen as a paraneoplastic syndrome (non-metastatic manifestation of malignancy). Polyneuropathy occurs in myeloma and other plasma cell dyscrasias via several mechanisms including: direct effects of paraproteins, amyloidosis and nerve infiltration, POEMS and effects of chemotherapy. Individual nerves may be infiltrated with malignant cells, e.g. lymphoma.

Neuropathies in systemic diseases

Vasculitic neuropathy occurs in SLE (p. 535), polyarteritis nodosa (p. 521), Churg–Strauss syndrome (p. 847), and rheumatoid disease (p. 543). Both multifocal neuropathy and symmetrical sensorimotor polyneuropathy occur.

Autonomic neuropathy

Autonomic neuropathy causes postural hypotension, urinary retention, erectile dysfunction, nocturnal diarrhoea, diminished sweating, impaired pupillary responses and cardiac arrhythmias. This can develop in diabetes and amyloidosis and may complicate Guillain–Barré syndrome and Parkinson's disease. Many varieties of neuropathy cause autonomic problems in a mild form. Occasionally, e.g. with amyloidosis, a severe autonomic neuropathy may occur.

Neuromuscular weakness complicating critical illness (p. 896)

Some 50% of critically ill ITU patients with multiple organ failure and/or sepsis develop an axonal polyneuropathy. Typically distal weakness and absent reflexes are seen during recovery from critical illness. Resolution is usual.

Plexus and nerve root lesions

The common conditions that cause these are summarized in Box 22.35.

Cervical and lumbar degeneration

Spondylosis (Tables 11.3, 11.6) describes vertebral and ligamentous degenerative changes occurring during ageing or following trauma. Several factors produce neurological signs and symptoms:

- Osteophytes – local overgrowth of bony spurs or bars
- Thickening of spinal ligaments
- Congenital narrowing of the spinal canal
- Disc degeneration and protrusion (posterior and lateral protrusion: cord and root compression)
- Vertebral collapse (osteoporosis, infection)
- Rheumatoid synovitis (p. 521)
- Ischaemic changes within cord and nerve roots.

Narrowing of disc spaces, osteophytes, narrowing of exit foramina, and narrowing of the spinal canal are also seen on X-rays and MRI in the *symptomless* population, commonly in the mid and lower cervical and lower lumbar region, and imaging must not be over interpreted.

Lateral cervical disc protrusion (Fig. 22.58)

The patient complains of pain in the arm. A C7 protrusion is the most common problem. There is root pain that radiates to the C7 myotome (triceps, deep to scapula and extensor aspect of forearm), with a sensory disturbance, tingling and numbness in the C7 dermatome.

**Box 22.35 Common root and plexus problems****Nerve root**

- Cervical and lumbar spondylosis
- Trauma
- Herpes zoster
- Tumours, e.g. neurofibroma, metastases
- Meningeal inflammation, e.g. syphilis, arachnoiditis

Plexus

- Trauma
- Malignant infiltration
- Neuralgic amyotrophy
- Thoracic outlet syndrome (cervical rib)

Figure 22.58 Central and lateral disc protrusions. (a) Central disc protrusion compressing cord. (b) Lateral disc protrusion compressing nerve roots.

In an established C7 root lesion there is:

- Weakness/wasting – triceps, wrist and finger extensors
- Loss of the triceps jerk (C7 reflex arc)
- C7 dermatome sensory loss.

Although the initial pain can be very severe, most cases recover with rest and analgesics. It is usual to immobilize the neck. Disc protrusion with root compression is seen on MRI. Root decompression is sometimes helpful.

Lateral lumbar disc protrusion

The L5 and S1 roots are commonly compressed by lateral prolapse of L4–L5 and L5–S1 discs – the root number below a disc interspace is compressed. There is low back pain and *sciatica*, i.e. pain radiating from the back to buttock and leg. Onset is typically acute. This can follow lifting, bending or minor injury. When pain follows such an event, it is tempting to ascribe the disc protrusion to it. However, lateral lumbar disc protrusion is commonly apparently spontaneous – lifting or injury is usually only bringing forward an inevitable disc prolapse.

Straight-leg raising is limited. There is reflex loss, e.g. ankle jerk in an S1 root lesion, weakness of plantar flexion (S1) or great toe extension (L5). Sensory loss is found in the affected dermatome.

Most sciatica resolves with initial rest and analgesia followed by early mobilization. MRI is sometimes appropriate: surgery is indicated when a substantial persistent symptomatic disc lesion is shown.

Acute low back pain

Acute low back pain is extremely common. Often pain is of disc or facet joint origin. Significant nerve root compression is unusual. Maintaining activity and a trial of gentle manipulation is recommended (see also p. 504).

Cervical spondylotic myelopathy

This is a relatively common disorder of older adults. Posterior disc protrusion (Fig. 22.59), common at C4–5, C5–6 and C6–7 levels, causes spinal cord compression. Congenital spinal canal narrowing, osteophytic bars, ligamentous thickening and ischaemia are contributory. Usually there are no or few neck symptoms. The patient complains of slowly progressive difficulty walking as a spastic paraparesis develops. A reflex level in the upper limbs and evidence of cervical radiculopathy may co-exist. MRI demonstrates the level and extent of cord compression and T2 signal change is usually

evident in the cervical cord at the point of maximal compression. Neck manipulation should be avoided.

Decompression by anterior cervical discectomy may be necessary when cord compression is severe or progressive. Complete recovery of the pyramidal signs may occur; progression is generally halted.

Central thoracic disc protrusion

Central protrusion of a thoracic disc is an unusual cause of paraparesis as the thoracic spine is relatively non-mobile and disc degeneration and protrusion, other than due to trauma, is rare.

The cauda equina syndrome

A central lumbosacral disc protrusion causes a *cauda equina syndrome*, i.e. bilateral flaccid (*cf.* spasticity in higher lesions) lower limb weakness, sacral numbness, retention of urine, erectile dysfunction and areflexia – usually with back pain. Multiple lumbosacral nerve roots are involved. Onset is either acute – an acute flaccid paraparesis – or chronic, sometimes with intermittent claudication. A central lumbosacral protrusion should be suspected if a patient with back pain develops retention of urine or sacral numbness. Urgent imaging and surgical decompression is indicated for this emergency. Neoplasms in the lumbosacral region can present with similar features.

Spinal stenosis

A narrow spinal canal is developmental and frequently symptomless but a congenital narrowing of the cervical canal predisposes the cervical cord to damage from minor disc protrusion later.

In the lumbosacral region, further narrowing of the canal by disc protrusion causes root pain, and/or buttock and lower limb claudication. As the patient walks, nerve roots become hyperaemic and swell, producing buttock and lower limb pain with numbness. Surgical decompression is required.

Neuralgic amyotrophy

Severe pain in muscles around one shoulder is followed by wasting, usually of infraspinatus, supraspinatus, deltoid and serratus anterior. A demyelinating brachial plexopathy develops over several days. The cause is unknown; an allergic or viral basis is postulated. Rarely, a similar condition develops in distal upper limb muscles or in a lower limb. Recovery of wasted muscles is usual, but not invariable, over several months.

Thoracic outlet syndrome

A fibrous band or cervical rib extending from the tip of the C7 transverse process towards the first rib compresses the lower brachial plexus roots, C8 and T1. There is forearm pain (ulnar border), T1 sensory loss and thenar muscle wasting, principally abductor pollicis brevis. Horner's syndrome may develop. The rib or band can be excised. Frequency of this diagnosis varies widely – thoracic outlet problems are sometimes invoked to explain ill-defined arm symptoms, typically on poor evidence.

A rib or band can also produce subclavian artery or venous occlusion. Neurological and vascular problems rarely occur together.

Malignant infiltration and radiation plexopathy

Metastatic disease of nerve roots, the brachial or lumbosacral plexus causes a painful radiculopathy and/or plexopathy.

Figure 22.59 C5/6 disc compressing cord: MR T2.

An example is apical bronchial carcinoma (Pancoast's tumour) causing a T1 and sympathetic outflow lesion – wasting of small hand muscles, pain and T1 sensory loss with ipsilateral Horner's syndrome. This also occurs in apical TB. In the upper limb, radiotherapy following breast cancer can produce a plexopathy.

MUSCLE DISEASES

Definitions

- **Myopathy** means a disease of voluntary muscle.
- **Myositis** indicates inflammation.
- **Muscular dystrophies** are inherited disorders of muscle cells.
- **Myasthenia** means fatiguable (worse on exercise) weakness – seen in neuromuscular junction diseases.
- **Myotonia** is sustained contraction/slow relaxation.
- **Channelopathies** are ion channel disorders of muscle cells.

Weakness is the predominant feature of muscle disease. A selection of these conditions is mentioned in [Box 22.36](#).

Pathophysiology

Muscle fibres are affected by:

- Acute inflammation and fibre necrosis (e.g. polymyositis, infection)
- Genetically determined metabolic failure (e.g. Duchenne muscular dystrophy)
- Infiltration by inflammatory tissue (e.g. sarcoidosis)
- Fibre hypertrophy and regeneration

Box 22.36 Muscle disease: classification

Acquired

- Inflammatory
- Polymyositis
- Dermatomyositis
- Inclusion body myositis
- Viral, bacterial and parasitic infection
- Sarcoidosis

Endocrine and toxic

- Corticosteroids/Cushing's
- Thyroid disease
- Calcium disorders
- Alcohol
- Drugs, e.g. statins

Myasthenic

- Myasthenia gravis
- Lambert–Eaton myasthenic-myopathic syndrome (LEMS)

Genetic dystrophies

- Duchenne
- Facioscapulohumeral
- Limb girdle, and others

Myotonic

- Myotonic dystrophy
- Myotonia congenita

Channelopathies

- Hypokalaemic periodic paralysis
- Hyperkalaemic periodic paralysis

Metabolic

- Myophosphorylase deficiency (McArdle's syndrome)
- Other defects of glycogen and fatty acid metabolism

Mitochondrial disease

- Mitochondrial diseases
- Immunological damage, e.g. myasthenia gravis and Lambert–Eaton myasthenic syndrome
- Ion channel disorders, e.g. chloride channel mutations in hereditary myotonias.

Diagnosis

Clinical features including the distribution of weakness, wasting or hypertrophy, and the tempo of progression and presence of family history help make a clinical diagnosis. Several investigations help make a definitive diagnosis:

Serum muscle enzymes

Serum creatine kinase (CK) is a marker of muscle fibre damage and is greatly elevated in many dystrophies, e.g. Duchenne, and in inflammatory muscle disorders, e.g. polymyositis.

Neurogenetic tests

These are essential in muscular dystrophies and mitochondrial disease.

Electromyography

Characteristic EMG patterns:

- **Myopathy**. Short-duration spiky polyphasic muscle action potentials are seen. Spontaneous fibrillation is occasionally recorded.
- **Myotonic discharges**. A characteristic high-frequency whine is heard.
- **Decrement and increment**. In myasthenia gravis, a characteristic decrement in evoked muscle action potential follows repetitive motor nerve stimulation. The reverse occurs, i.e. increment, following repetitive stimulation in LEMS, [page 1152](#).
- In **denervation**, profuse fibrillation potentials are seen.

Muscle biopsy

Unlike neural tissue skeletal muscle can be easily biopsied to provide a definitive diagnosis using powerful molecular immunohistochemical techniques. Histology and muscle histochemistry of fibre types demonstrate denervation, inflammation and dystrophic changes. Electron microscopy is often valuable. In dystrophies immunohistochemistry in specialist labs allows identification of the abnormal muscle protein and a precise molecular diagnosis.

Imaging

MRI shows *signal changes* within muscles in some cases of myositis and fatty replacement of muscle in chronically damaged muscles.

Inflammatory myopathies

Inflammatory myopathies including polymyositis, dermatomyositis and inclusion body myositis are described on [page 541](#). Granulomatous muscle infiltration and inflammation may occur in sarcoidosis and other disorders such as rheumatoid arthritis, causing a mild myopathy. Viral myositis may also occur and muscles may be involved in other infections such as neurocysticercosis ([p. 1130](#)).

Metabolic and endocrine myopathies

Corticosteroids and Cushing's syndrome

Proximal weakness occurs with prolonged high-dose steroid therapy and in Cushing's syndrome ([p. 943](#)). Selective type-2 fibre atrophy is seen on biopsy.

Thyroid disease

Several myopathies occur (see also p. 965). Thyrotoxicosis can be accompanied by severe proximal myopathy. There is also an association between thyrotoxicosis and myasthenia gravis, and between thyrotoxicosis and hypokalaemic periodic paralysis (p. 1153). Both associations are seen more frequently in South-east Asia. In ophthalmic Graves' disease, there is swelling and lymphocytic infiltration of extraocular muscles (p. 967).

Hypothyroidism is sometimes associated with muscle pain and stiffness, resembling myotonia. A proximal myopathy also occurs.

Disorders of calcium and vitamin D metabolism

Proximal myopathy develops in hypocalcaemia, rickets and osteomalacia (p. 559).

Hypokalaemia

Acute hypokalaemia (e.g. with diuretics) causes flaccid paralysis reversed by potassium, given slowly (p. 654). Chronic hypokalaemia leads to mild, mainly proximal, weakness. (See also periodic paralysis (p. 1080)).

Alcohol and drugs

Severe myopathy with muscle pain, necrosis and myoglobinuria occurs in acute excess. A subacute proximal myopathy occurs with chronic alcohol use. A similar syndrome occurs in diamorphine and amphetamine addicts.

Drugs

Drug-induced muscle disorders include proximal myopathy (steroids), muscle weakness (lithium), painful muscles (fibrates), rhabdomyolysis (fibrate combined with a statin or interaction between statins and other drugs such as certain antibiotics) and malignant hyperpyrexia. Most respond to drug withdrawal.

Myophosphorylase deficiency (McArdle's syndrome)

See page 1039.

Malignant hyperpyrexia

Widespread skeletal muscle rigidity with hyperpyrexia as a sequel of general anaesthesia or neuroleptic drugs, e.g. haloperidol, is due to a genetic defect in the sarcoplasmic reticulum calcium-release channel of the muscle ryanodine receptor, RyR1. Death during or following anaesthesia can occur in this rarity, sometimes inherited as an autosomal dominant. Dantrolene is of some help for rigidity.

Neuromuscular junction disorders

Myasthenia gravis (MG)

MG is an acquired and probably heterogeneous condition. It is characterized by weakness and fatiguability of proximal limb, bulbar and ocular muscles, the latter sometimes in isolation. The heart is not affected. The prevalence is about 4 in 100 000. MG is twice as common in women as in men, with a peak age incidence around 30. The underlying cause is unknown.

Antibodies to acetylcholine receptor protein (anti-AChR antibodies) are commonly found. Immune complexes of anti-AChR IgG and complement are deposited at the postsynaptic membranes, causing interference with and later destruction of AChRs.

A second group of antibodies against muscle-specific receptor tyrosine kinase (anti-MuSK antibodies) have been identified in anti-AChR antibody negative cases. Ocular muscle MG is another subgroup.

Thymic hyperplasia is found in 70% of MG patients below the age of 40. In some 10%, a thymic tumour is found, the incidence increasing with age; antibodies to striated muscle can be demonstrated in some of these patients. Young patients without a thymoma have an increased association with HLA-B8 and DR3.

There is an association between MG and thyroid disease, rheumatoid disease, pernicious anaemia and SLE. Transient MG is sometimes caused by D-penicillamine treatment.

Clinical features

Fatiguability is typical. Limb muscles (proximal), extraocular, speech, facial expression and mastication muscles are commonly affected. Respiratory difficulties can be prominent. The clinical picture of fluctuating, fatigable weakness is usually diagnostic. Muscle pain is typically absent. Early complaints of fatigue are frequently dismissed.

Complex extraocular palsies, ptosis and fluctuating proximal weakness are found. The reflexes are initially preserved but may be fatigable, i.e. disappear following repetitive activity. Wasting is sometimes seen after many years.

Investigations

■ Serum anti-AChR and anti-MuSK antibodies.

Anti-AChR antibodies are present in some 80–90% of cases of generalized MG. These antibodies are not found in healthy controls but are seen rarely in other muscle disorders. In pure ocular MG, anti-AChR antibodies are detectable in less than 30% of cases.

Anti-MuSK antibodies define a subgroup of MG patients characterized by weakness predominantly in bulbar, facial and neck muscles.

■ Repetitive nerve stimulation. A characteristic decrement occurs in the evoked muscle action potential during repetitive stimulation. EMG is otherwise normal.

■ **Tensilon (edrophonium) test.** This is seldom required and the drug is not available worldwide. Edrophonium 10 mg is given intravenously following a 1–2 mg test dose from the 10 mg vial. When the test is positive, there is substantial improvement in weakness within seconds and this lasts for up to 5 minutes. Perform a control test using saline and have an observer. The sensitivity of the test is 80% but there are false negative and positive tests. Occasionally, edrophonium (an anticholinesterase) causes bronchospasm and syncope. Resuscitation facilities must be available.

■ **Imaging and other tests.** Mediastinal MR provides optimal structural imaging for thymoma. Routine blood studies are normal: the ESR is not raised, and CPK is normal. Antibodies to striated muscle suggest a thymoma; intrinsic factor and thyroid antibodies may be found. Rheumatoid factor and anti-nuclear antibody tests can be positive. Muscle biopsy is usually not performed, though ultrastructural neuromuscular junction abnormalities are well described.

Course and management

Myasthenia gravis fluctuates in severity; most cases have a protracted, lifelong course. Respiratory impairment, nasal regurgitation and dysphagia occur; emergency assisted ventilation may be required. Simple monitoring tests, such as the duration for which an arm can be held outstretched, and the vital capacity are useful.

Exacerbations are usually unpredictable and unprovoked but may be brought on by infections and by aminoglycosides. Magnesium sulphate enemas can provoke severe weakness.

Treatment

Oral anticholinesterases

Pyridostigmine (60 mg tablet) is widely used. The duration of action is 3–4 hours, the dose (usually 4–16 tablets daily) determined by response. Pyridostigmine prolongs acetylcholine action by inhibiting cholinesterase. Overdose of anticholinesterases causes severe weakness (cholinergic crisis). Muscarinic side-effects, e.g. colic and diarrhoea, are common; oral atropine (antimuscarinic) 0.5 mg helps to reduce this. Anticholinesterases help weakness but do not alter the natural history of myasthenia.

Immunosuppressant drugs

These drugs are used in patients who do not respond to pyridostigmine or who relapse on treatment. Steroids are often used. There is improvement in 70%, although this may be preceded by an initial relapse. Azathioprine, mycophenolate and other immunosuppressants are also used.

Thymectomy

Thymectomy improves prognosis, more so in women than men below 50 years with positive AchR antibodies, even in patients without a thymoma. Cases positive for anti-MuSK antibodies tend not to improve following thymectomy. When a thymoma is present, the potential for malignancy also makes surgery necessary.

Plasmapheresis and intravenous immunoglobulin

During exacerbations these interventions are of value.

Other rare myasthenic syndromes exist, e.g. congenital myasthenia.

Lambert-Eaton myasthenic-myopathic syndrome (LEMS)

This paraneoplastic manifestation of small-cell bronchial carcinoma is due to defective acetylcholine release at the neuromuscular junction. Proximal limb muscle weakness, sometimes with ocular/bulbar muscles develops, with some absent tendon reflexes, a cardinal sign. Weakness tends to improve after a few minutes of muscular contraction, and absent reflexes return (*cf.* myasthenia). Diagnosis is confirmed by EMG and repetitive stimulation (increment, see above). Antibodies to P/Q-type voltage-gated calcium channels are found in most cases (90%). 3,4-Diaminopyridine (DAP) is a reasonably safe and sometimes effective treatment.

Muscular dystrophies

These progressive genetically determined disorders of skeletal and sometimes cardiac muscle have a complex clinical and neurogenetic classification.

Duchenne muscular dystrophy (DMD) and Becker's muscular dystrophy

These are inherited as X-linked recessive disorders, though one-third of cases are spontaneous mutations. DMD occurs in 1 in 3000 male infants. There is absence of the gene product *dystrophin*, a rod-shaped cytoskeletal muscle protein in DMD. In Becker's dystrophy dystrophin levels are present but low. DMD is usually obvious by the 4th year, and often causes death by the age of 20.

Dystrophin is essential for cell membrane stability. Deficiency leads to reduction in three glycoproteins (α -, β - and γ -sarcoglycans) in the dystrophin-associated protein complex (DAP-complex) that link dystrophin to laminin within cell membranes.

Becker's muscular dystrophy is less severe than Duchenne and weakness only becomes apparent in young adults.

Clinical features

A boy with DMD is noticed to have difficulty running and rising to his feet – he uses his hands to climb up his legs (Gowers' sign). There is initially a proximal limb weakness with calf pseudohypertrophy. The myocardium is affected. Severe disability is typical by the age of 10.

Investigations

The diagnosis is often suspected clinically. CK is grossly elevated (100–200 \times normal). Biopsy shows variation in muscle fibre size, necrosis, regeneration and replacement by fat, and on immunochemical staining, absence of dystrophin.

Management

There is no curative treatment. Passive physiotherapy helps prevent contractures in the later stages. Portable respiratory support improves life expectancy.

Carrier detection. Females with an affected brother have a 50% chance of carrying the DMD gene. In carriers, 70% have a raised CK, usually EMG abnormalities and/or changes on biopsy. Carrier and prenatal diagnosis are available with genetic counselling.

Limb-girdle and facioscapulohumeral dystrophy

These less severe but disabling dystrophies are summarized in Table 22.27. There are many other varieties of dystrophy. Many are associated with a sarcoglycan deficiency. Genes for numerous limb-girdle muscular dystrophies (LGMD) have been identified.

Myotonias

Myotonias are characterized by continued, involuntary muscle contraction after cessation of voluntary effort, i.e. failure of muscle relaxation. EMG is characteristic (p. 1090). The two most common myotonias are described below. Patients with myotonia tolerate general anaesthetics poorly.

Table 22.27 Limb-girdle and facioscapulohumeral dystrophies

	Limb-girdle	Facioscapulohumeral
Inheritance	Autosomal, various	Dominant, usually
Onset	10–20 years	10–40 years
Muscles affected	Shoulders, pelvic girdle	Face, shoulders, pelvic girdle
Progress	Severe disability <25 years	Life expectancy normal, slow progress
Hypertrophy	Rare	Very rare

Myotonic dystrophy (MD)

This autosomal dominant condition is a genetic disorder with two different triple repeat mutations, most commonly an expanded CTG repeat in a protein-kinase (*DMPK*) gene (DM1). The less common variety (DM2) is caused by expanded CCTG repeat in a zinc finger protein gene. There is a correlation between disease severity, age at onset and approximate size of triple repeat mutations. There is progressive distal muscle weakness, with ptosis, weakness and thinning of the face and sternomastoids. Myotonia is typically present. Muscle disease is part of a syndrome comprising:

- Cataracts
- Frontal baldness
- Cognitive impairment (mild)
- Oesophageal dysfunction (and aspiration)
- Cardiomyopathy and conduction defects (sudden death can occur in type 1)
- Small pituitary fossa and hypogonadism
- Glucose intolerance
- Low serum IgG.

This gradually progressive condition usually becomes evident between 20 and 50 years. Phenytoin or procainamide sometimes helps the myotonia.

Myotonia congenita

Autosomal dominant myotonia, usually mild, becomes evident in childhood. The gene, *CLC1*, codes for a muscle chloride channel. The myotonia, which persists, is accentuated by rest and by cold. Diffuse muscle hypertrophy occurs – the patient has bulky muscles.

Channelopathies

The common feature in these genetic disorders is malfunction of muscle membrane ion channels.

Hypokalaemic periodic paralysis

This disorder is characterized by generalized weakness, including bulbar muscles, that often starts after a heavy carbohydrate meal or following exertion. Attacks last for several hours. It often first comes to light in the teenage years and tends to remit after the age of 35. Serum potassium is usually below 3.0 mmol/L in an attack. The weakness responds to (slow) i.v. potassium chloride. It is usually an autosomal dominant trait caused by mutation in a muscle voltage-gated calcium channel gene (*CACLN1A3*). Other mutations in the sodium channels (*SCNA4*) and potassium channels (*KCNE3*) also occur. Acetazolamide sometimes helps prevent attacks. Weakness can be caused by diuretics. A similar condition can also occur with thyrotoxicosis.

Hyperkalaemic periodic paralysis

This condition, also autosomal dominant, is characterized by attacks of weakness, sometimes with exercise. Attacks start in childhood and tend to remit after the age of 20; they last about 30–120 min. Myotonia may occur. Serum potassium is elevated. An attack can be terminated by i.v. calcium gluconate or chloride. There are point mutations in a muscle voltage-gated sodium channel gene (*SCN4A*). Acetazolamide or a thiazide diuretic can be helpful.

A very rare normokalaemic, sodium-responsive periodic paralysis also occurs.

Stiff person syndrome

Stiff person syndrome (SPS) is a rare autoimmune disease, commoner in females, causing axial muscle stiffness with abnormal posture, spasms and falls. Attacks of stiffness are sometimes provoked by noise or emotion, but sometimes occur spontaneously. Between attacks, which last from hours to days or even weeks, the patient may appear normal.

Widespread muscle stiffness is typical during an attack; there are no other neurological signs. SPS has been mistaken for Parkinson's, dystonia and non-organic conditions. Anti-glutamic acid decarboxylase antibodies (anti-GAD) are found in very high titre in >50% of cases and are believed to be involved in the generation of muscle stiffness. Continuous motor activity in paraspinal muscles is seen on EMG.

Treatment with diazepam, other muscle relaxants and i.v. immunoglobulin can be helpful during attacks.

A form of SPS is also seen occasionally as a paraneoplastic condition associated with antibodies to the synaptic protein amphiphysin (p. 437).

Mitochondrial diseases

These comprise a complex group of rare disorders involving muscle, peripheral nerves and CNS, characterized by morphological and biochemical abnormalities in mitochondria. Mitochondrial DNA is inherited maternally (p. 37). The spectrum is wide, ranging from optic atrophy (see Leber's, p. 35) to myopathies, neuropathies and encephalopathy.

- *MELAS* (mitochondrial encephalomyopathy, lactic acidosis, stroke-like episodes) is one well-recognized form.
- Chronic progressive ophthalmoplegia (CPEO) is another.
- *MERRF* describes myoclonic epilepsy with abnormal muscle histology, the muscle appearance being described as *ragged red fibres*.

INTRODUCTION

Psychiatry is concerned with the study and management of disorders of mental function: primarily thoughts, perceptions, emotions and purposeful behaviours. Psychological medicine, or liaison psychiatry, is the discipline within psychiatry that is concerned with psychiatric and psychological disorders in patients who have physical complaints or conditions. This chapter will primarily concern itself with this particular branch of psychiatry.

The long-held belief that diseases are either physical or psychological has been replaced by the accumulated evidence that the brain is functionally or anatomically abnormal in most if not all psychiatric disorders. Physical, psychological and social factors, and their interactions must be looked into, in order to understand psychiatric conditions. This philosophical change of approach rejects the Cartesian dualistic approach of the mind/body *biomedical model* and replaces it with the more integrated *biopsychosocial model*.

Epidemiology (Box 23.1)

The prevalence of psychiatric disorders in the community in the UK is about 20%, mainly composed of depressive and anxiety disorders and substance misuse (mainly alcohol). The prevalence is about twice as high in patients attending the general hospital, with the highest rates in the accident and emergency department and medical wards.

Culture and ethnicity

These can alter either the presentation or the prevalence of psychiatric ill-health. Biological factors in mental illness are usually similar across cultural boundaries, whereas psychological and social factors will vary. For example, the

prevalence and presentation of schizophrenia vary little between countries, suggesting that biological/genetic factors are operating independently of cultural factors. In contrast, disorders in which social factors play a greater role vary between cultures, so that anorexia nervosa is found more often in developed cultures. Culture can also influence the presentation of illnesses, such that physical symptoms are more common presentations of depressive illness in Asia than in Europe. Similarly culture will influence the healthcare sought for the same condition.

THE PSYCHIATRIC HISTORY

As in any medical specialty, the history is essential in making a diagnosis. It is similar to that used in all specialties but tailored to help to make a psychiatric diagnosis, determine possible aetiology, and estimate prognosis. Data may be taken from several sources, including interviewing the patient, a friend or relative (usually with the patient's permission), or the patient's general practitioner. The patient interview also enables a doctor to establish a therapeutic relationship with the patient. Box 23.2 gives essential guidance on how to safely conduct such an interview, although it is unlikely that a patient will physically harm a healthcare professional. When interviewing a patient for the first time, follow the guidance outlined in Chapter 1 (see pp. 10–12).

Components of the history are summarized in Table 23.1.

THE MENTAL STATE EXAMINATION (MSE)

The history will already have assessed several aspects of the MSE, but the interviewer will need to expand several areas

as well as test specific areas, such as cognition. The MSE is typically followed by a physical examination and is concluded with an assessment of insight, risk and a formulation that takes into account a differential diagnosis and aetiology. Each domain of the MSE is given below; abnormalities that might be detected and the disorders in which they are found

Box 23.1 The approximate prevalence of psychiatric disorders in different populations

	Approximate percentage
Community	20
Neuroses	16
Psychoses	0.5
Alcohol misuse	5
Drug misuse	2 (an underestimate)
(total in community 20% due to co-morbidity)	
Primary care	25
General hospital outpatients	30
General hospital inpatients	40

Box 23.2 The essentials of a safe psychiatric interview

- Beforehand: Ask someone of experience who knows the patient whether it is safe to interview the patient alone.
- Access to others: If in doubt, interview in the view or hearing of others, or accompanied by another member of staff.
- Setting: If safe; in a quiet room alone for confidentiality, not by the bed.
- Seating: Place yourself between the door and the patient.
- Alarm: If available, find out where the alarm is and how to use it.

are summarized in Table 23.2. The major subheadings are listed below.

Appearance and general behaviour

State and colour of clothes, facial appearance, eye contact, posture and movement provide information about a patient's affect. Agitation and anxiety cause an easy startle response, sweating, tremor, restlessness, fidgeting, visual scanning (for danger) and even pacing up and down.

Speech

The rate, rhythm, volume and content of the patient's speech should be examined for abnormalities. Note that speech is the only way that one can examine thoughts and as such, disorders of thought are typically seen in this section of the examination. Thought content (literally the content of their thoughts) is dealt with separately (see below). Abnormalities that may reflect neurological lesions, such as dysarthria and dysphasia, should also be assessed.

Mood and affect

The patient has an *emotion* or *feeling*, tells the doctor about their *mood*, and the doctor observes the patient's *affect*. In psychiatric disorders, mood may be altered in three ways: a persistent change in mood, a fluctuating mood and an incongruous mood.

Thoughts

In addition to those abnormalities looked at under 'speech' (see above), abnormalities of thought content and thought possession are discussed here. Delusions (Table 23.2) can be further categorized as primary or secondary. Depending on whether they arise *de novo* or in the context of other abnormalities in mental state.

Table 23.1 Summary of the components of the psychiatric history

Component	Description
Reason for referral	Why and how the patient came to the attention of the doctor
Present illness	How the illness progressed from the earliest time at which a change was noted until the patient came to the attention of the doctor
Past psychiatric history	Prior episodes of illness, where were they treated and how? Prior self-harm
Past medical history	Include emotional reactions to illness and procedures
Family history	History of psychiatric illnesses and relationships within the family
Personal (biographical) history	Childhood: Pregnancy and birth (complications, nature of delivery), early development and attainment of developmental milestones (e.g. learning to crawl, walk, talk). School history: age started and finished; truancy, bullying, reprimands; qualifications Adulthood: Employment (age of first, total number, reasons for leaving, problems at work), relationships (sexual orientation, age of first, total number, reasons for endings of relationships), children and dependants
Reproductive history	In women: include menstrual problems, pregnancies, terminations, miscarriages, contraception and the menopause
Social history	Current employment, benefits, housing, current stressors
Personality	This may help to determine prognosis. How do they normally cope with stress? Do they trust others and make friends easily? Irritable? Moody? A loner? This list is not exhaustive
Drug history	Prescribed and over-the-counter medication, units and type of alcohol/week, tobacco, caffeine and illicit drugs
Forensic history	Explain that you need to ask about this, since ill-health can sometimes lead to problems with the law. Note any violent or sexual offences. This is part of a <i>risk assessment</i> . Worst harm they have ever inflicted on someone else? Under what circumstances? Would they do the same again were the situation to recur?
Systematic review	Psychiatric illness is not exclusive of physical illness! The two may not only co-exist but may also have a common aetiology

Table 23.2 The mental state examination and the psychopathology it is used to detect			
Appearance and behaviour	Colour and state of clothes, facial appearance, eye contact, posture, movement, agitation. Startle response, sweating, tremor, restlessness, fidgeting, visual scanning (for danger), distractibility		
	Abnormality	Description	Typical of which disorder(s)?
Speech			
Disorders of the stream of thought	Pressured speech	Rapid rate, increased volume, difficult to interrupt	Mania
	Poverty of speech	Lengthy pauses between brief utterances	Depressive illness Schizophrenia
	Thought block	A sentence is suddenly stopped for no obvious reason	Schizophrenia
Disorders of thought form	Flight of ideas	Thoughts rapidly jump from one topic to another	Mania
	Word salad or schizophasia	The connection between themes, sentences and even words is lost, resulting in unintelligible speech, although words are still identifiable	Schizophrenia Receptive (Wernicke's) aphasia
	Perseveration	Persistent, inappropriate repetition of the same thought or action	Schizophrenia, Obsessive-compulsive disorder Frontal lobe lesions
Mood			
Persistent change	Depression	Low mood, tearfulness, low spirits	Depression
	Anxiety	Constant, inappropriate or excessive worry, fear, apprehension, tension or inner restlessness	Anxiety disorders (± depressive illnesses) Drug intoxication and withdrawal
	Elation	A feeling of high spirits, exuberant happiness, vitality	Mania, drug intoxication
	Irritability	Either expressed (as in a temper or impatience) or an internal feeling of exasperation or anger	Depression (especially men) Mania
	Blunted affect	A total absence of emotion	Schizophrenia (in chronic illness)
Fluctuating change		Different emotions rapidly follow one another. Alternatively, excessively emotional over events	Mixed affective states Pseudobulbar palsy
Incongruity		Mood and context do not reflect one another, e.g. laughing whilst describing the death of a loved one	Schizophrenia Mania
Thoughts			
Disorders of content	Delusions	A false belief held with absolute conviction, and out of keeping with the patient's cultural, social and religious beliefs	Psychosis
	Overvalued ideas	Deeply held personal convictions that are understandable when the individual's background is known	
	Obsessions	Recurrent, persistent thought, impulse, image or musical theme occurring despite the patient's effort to resist it. May be accompanied by compulsions (repetitive, seemingly purposeful action performed stereotypically)	Obsessive-compulsive disorder
Disorders of thought possession	Thought broadcast	The patient experiences their thoughts as being understood by others without talking	Schizophrenia
	Thought insertion	The patient's thought is perceived as being planted in their mind by someone else	Schizophrenia
	Thought withdrawal	The patient experiences their thoughts being taken away from them, without their control	Schizophrenia

Continued

Introduction

The psychiatric history

The mental state examination (MSE)

Table 23.2 The mental state examination and the psychopathology it is used to detect—cont'd

Abnormality	Description	Typical of which disorder(s)?
Perceptions		
Hallucinations	Perception in the absence of a stimulus, perceived in objective space with the qualities of normal perceptions	Psychosis Organic brain states, e.g. delirium
Pseudo-hallucinations	Usually auditory: true externally sited hallucinations, but with insight into their imaginary nature, or internally sited (e.g. 'I heard a voice in my head speaking to me')	Depressive illness Personality disorders Not indicative of psychotic disorder
Illusions	Misperceptions of external stimuli, most likely when the general level of sensory stimulation is reduced	Normal experience Some neurological disorders
Depersonalization	A change in self-awareness such that the patient feels unreal or detached from their body. The patient is aware, however, of the subjective nature of this alteration	Anxiety disorders Schizophrenia Temporal lobe epilepsy, in healthy people when tired
Derealization	The unpleasant feeling that the external environment has become unreal and/or remote; patients may describe themselves as though they are in a dream-like state	As in depersonalization
Heightened sensitivity	Photosensitivity and phonosensitivity	Anxiety disorders Drug intoxication and withdrawal Migraine Epilepsy

Abnormal perceptions

The assessment of perceptions in the mental state involves observation of the patient as well as asking questions of them. For example, patients experiencing auditory hallucinations may appear startled by sounds or voices that you cannot hear or may interact with them, e.g. appearing to be engaged in conversation when nobody else is in the room.

Hallucinatory phenomena can affect any sensory modality and specific types of hallucination will be dealt with later in the chapter with the disorders in which they most commonly occur.

Cognitive state

Examination of the cognitive state is necessary to diagnose organic brain disorders, such as delirium and dementia. Poor concentration, confusion and memory problems are the most common subjective complaints. Clinical testing involves the screening of cognitive functions, which may suggest the need for more formal psychometry. A premorbid estimate of intelligence, necessary to judge changes in cognitive abilities, can be made from asking the patient the final year level of education and the highest qualifications or skills achieved.

Testing can be divided into tests of diffuse and focal brain functions.

Diffuse functions

- **Orientation** in time, place and person. Consciousness can be defined as the awareness of the self and the environment. Clouding of consciousness is more accurately a fluctuating level of awareness and is commonly seen in delirium.
- **Attention** is tested by saying the months or days backwards.
- **Verbal memory.** Ask the patient to repeat a name and address with 10 or so items, noting how many times it takes to recall it 100% accurately (normal is 1 or 2) (immediate recall or registration).

- Ask the patient to try to remember it and then ask it of them again after 5 min (0 or 1 error is normal) (short-term memory).

- **Long-term memory.** Ask the patient to recall the news of that morning or recently. If they are not interested in the news, find out their interests and ask relevant questions (about their football team or favourite soap opera). *Amnesia* is literally an absence of memory and *dysmnnesia* indicates a dysfunctioning memory.

Focal functions

Frontal, temporal and parietal function tests are covered in chapter 22. Note any disinhibited behaviour not explained by another psychiatric illness. *Sequential tasks* are tested by asking the patient to alternate making a fist with one hand at the same time as a flat hand with the other. Ask the patient to tap a table once if you tap twice and vice-versa. Note any motor perseveration whereby the patient cannot change the movement once established. Observe for verbal perseveration, in which the patient repeats the same answer as given previously for a different question. *Abstract thinking* is measured by asking the meaning of common proverbs, a literal meaning suggesting frontal lobe dysfunction, assuming reasonable premorbid intelligence.

Assessing cognitive dysfunction

Questions on: orientation (e.g. time, date, place); registration (naming objects); attention and calculation (simple arithmetic); recall (previously mentioned objects); and language (understanding commands). This correlates well with more time-consuming intelligence quotient (IQ) tests, but it will not as easily pick up cognitive problems caused by focal brain lesions. Simple questioning will detect about 90% of people with cognitive impairments, with about 10% false positives.

Insight and illness beliefs

Insight is the degree to which a person recognizes that he or she is unwell, and is minimal in people with a psychosis. *Illness beliefs* are the patient's own explanations of their ill

Table 23.3 The assessment of risk

	Risk to self	Risk to others
Active	Acts of self-harm or suicide attempts Look for prior history of self-harm and what may have precipitated or prevented it	Aggression towards others – this may be actual violence or threatening behaviour A past history of aggression is a good predictor of its recurrence. Look at the severity and quality of and remorse for prior violent acts as well as identifiable precipitants that might be avoided in the future (e.g. alcohol)
Passive	Self-neglect Manipulation by others	Neglect of others – always find out whether children or other dependants are at home

health, including diagnosis and causes. These beliefs should be elicited because they can help to determine prognosis and adherence with treatment, whatever the diagnosis.

Risk

The assessment of risk may sound daunting but it is fundamental to clinical practice; for instance when determining whether a patient presenting with chest pain should be reviewed in the resuscitation room of the emergency department rather than a normal cubicle. Risk must be assessed in people with a psychiatric diagnosis, albeit that the nature of 'risk' is different.

Risk can be broken down into two parts: the risk that the patient poses to themselves and that which they pose to others (Table 23.3). You will have already made an appraisal of risk in your initial preparations for seeing the patient (Box 23.2) and in checking 'forensic history' (Table 23.1). It may be necessary to obtain additional information from family, friends or professionals who know the patient – this may save time and prove invaluable.

Severe behavioural disturbance

Patients who are aggressive or violent cause understandable apprehension in all staff, and are most commonly seen in the accident and emergency department. Information from anyone accompanying the patient, including police or carers, can help considerably. Box 23.3 gives the main causes of disturbed behaviour.

Management of the severely disturbed patient

The primary aims of management are control of dangerous behaviour and establishment of a provisional diagnosis. Three specific strategies may be necessary when dealing with the violent patient:

- Reassurance and explanation
- Medication.
- Physical restraint.

Remember that the behaviour exhibited is a reflection of an underlying disorder and as such portrays suffering and often fear. The approach to the agitated or even the violent patient therefore must take this into account and the steps used are with the intention of alleviating this suffering whilst maintaining the safety of the individual, the other patients and staff. Technically speaking, this management begins at the point of an initial assessment that takes into account

Box 23.3 Main causes of disturbed behaviour

- Drug intoxication (especially alcohol)
- Delirium (acute confusional state)
- Acute psychosis
- Personality disorder

prior episodes of disturbed behaviour and its precipitants. Armed with this knowledge it may be possible to prevent a recurrence.

'Verbal de-escalation'. If a patient's behaviour causes concern, the first step is to try and defuse the situation. Put more simply, this means talking to the patient. It may be something that is relatively simple to correct that has led to the disturbed behaviour such as staff explaining their intentions in approaching the patient.

Medication may be used but an effort should always be made to offer this on an oral basis. The protocol in the UK is to offer a short-acting benzodiazepine in the first instance, such as lorazepam (0.5–1 mg). Patients suffering from a psychotic disorder and who are already taking antipsychotics may be more appropriately treated with an antipsychotic but do not assume that this is the case and be wary of the 'neuroleptic-naïve' patient. In the delirious or elderly patient, benzodiazepines should be avoided, as they may worsen any underlying confusion and can cause paradoxical agitation. In this instance, low-dose haloperidol is appropriate (2.5–5 mg). More recently, antihistamines have been added to this protocol, such as promethazine. Medications should be given sequentially, rather than all at once, where possible and allowing between 30 min and 1 h for them to take effect.

Physical restraint. In the instance that the above measures do not resolve the situation, physical restraint may be necessary in order to maintain safety and to administer medications on an intramuscular basis (note that for haloperidol this will alter the maximum dose it is safe to use in a 24-hour period). This should not be the first step taken nor should it be performed by staff unless they have been adequately trained in approved methods of control and restraint. This will typically mean nursing staff on a psychiatric ward or security staff on a general medical or surgical ward. Although this may vary between countries, in the UK it is the case that doctors will never be involved in the restraint of the patient. Restraint is a potentially dangerous intervention, even more so when mixed with psychotropic medication, and deaths have occurred as a direct consequence.

Monitoring. If medications (oral or otherwise) are employed, with or without restraint, regular monitoring of physical parameters such as blood pressure, pulse, respiratory rate and oxygen saturation should be performed at a frequency dictated by the level of ongoing agitation and consciousness.

Defence mechanisms

Although not strictly part of the mental state examination, it is useful to be able to identify psychological defences in ourselves and our patients. Defence mechanisms are mental processes that are usually unconscious. Some of the most commonly used defence mechanisms are described in Table 23.4 and are useful in understanding many aspects of behaviour.

The relevant physical examination

This should be guided by the history and mental state examination. Particular attention should usually be paid to

Table 23.4 Common defence mechanisms

Defence mechanism	Description
Repression	Exclusion from awareness of memories, emotions and/or impulses that would cause anxiety or distress if allowed to enter consciousness
Denial	Similar to repression and occurs when patients behave as though unaware of something that they might be expected to know, e.g. a patient who, despite being told that a close relative has died, continues to behave as though the relative were still alive
Displacement	Transferring of emotion from a situation or object with which it is properly associated to another that gives less distress
Identification	Unconscious process of taking on some of the characteristics or behaviours of another person, often to reduce the pain of separation or loss
Projection	Attribution to another person of thoughts or feelings that are in fact one's own
Regression	Adoption of primitive patterns of behaviour appropriate to an earlier stage of development. It can be seen in ill people who become child-like and highly dependent
Sublimation	Unconscious diversion of unacceptable behaviours into acceptable ones

the neurological and endocrinological examinations when organic brain syndromes and affective illnesses are suspected.

Summary or formulation

When the full history and mental state have been assessed, the doctor should make a concise assessment of the case, which is termed a formulation. In addition to summarizing the essential features of the history and examination, the formulation includes a differential diagnosis, a discussion of possible causal factors, and an outline of further investigations or interviews needed. It concludes with a concise plan of treatment and a statement of the likely prognosis.

CLASSIFICATION OF PSYCHIATRIC DISORDERS

The classification of psychiatric disorders into categories is mainly based on symptoms and behaviours, since there are currently few diagnostic tests for psychiatric disorders. There currently exists an unhelpful dualistic division of psychiatric disorders from neurological diseases, since the pathologies of at least the majority of each group of conditions are located in the brain, e.g. Alzheimer's disease causing dementia and a pseudobulbar palsy causing emotional lability.

Psychiatric classifications have traditionally divided up disorders into neuroses and psychoses.

- **Neuroses** are illnesses in which symptoms vary only in severity from normal experiences, such as depressive illness.

Table 23.5 International classification of psychiatric disorders (ICD-10)

Organic disorders
Mental and behavioural disorders due to psychoactive substance use
Schizophrenia and delusional disorders
Mood (affective) disorders
Neurotic, stress-related and somatoform disorders
Behavioural syndromes
Disorders of adult personality and behaviour
Mental retardation

- **Psychoses** are illnesses in which symptoms are qualitatively different from normal experience, with little insight into their nature, such as schizophrenia.

There are several problems with a neurotic-psychotic dichotomy. First, neuroses may be as severe in their effects as psychoses. Second, neuroses may cause symptoms that fulfil the definition of psychotic symptoms. For instance, someone with anorexia nervosa may be convinced that they are fat when they are thin, and this belief would meet all the criteria for a delusional belief. Yet we would traditionally classify the illness as a neurosis.

The ICD-10 Classification of Mental and Behavioural Disorders published by the World Health Organization has largely abandoned the traditional division between neurosis and psychosis, although the terms are still used. The disorders are now arranged in groups according to major common themes (e.g. mood disorders and delusional disorders). A classification of psychiatric disorders derived from ICD-10 is shown in Table 23.5, and this is the classification mainly used in this chapter (ICD-11 will be available in 2014).

The **Diagnostic and Statistical Manual of the American Psychiatric Association (DSM-IV-TR)** is an alternative classification system (DSM-V in 2013).

CAUSES OF A PSYCHIATRIC DISORDER

A psychiatric disorder may result from several causes which may interact. It is most helpful to divide causes into the three 'Ps': predisposing, precipitating and perpetuating factors.

- **Predisposing factors** often stem from early life and include genetic, pregnancy and delivery, previous emotional traumas and personality factors.
- **Precipitating (triggering) factors** may be physical, psychological or social in nature. Whether they produce a disorder depends on their nature, severity and the presence of predisposing factors. For instance a death of a close, rather than distant, family member is more likely to precipitate a pathological grief reaction in someone who has not come to terms with a previous bereavement.
- **Perpetuating (maintaining) factors** prolong the course of a disorder after it has occurred. Again they may be physical, psychological or social, and several are often active and interacting at the same time. For example, high levels of criticism at home combined with taking cannabis, as relief from the criticism, may help to maintain schizophrenia.

Classification of psychiatric disorders**Causes of a psychiatric disorder****Psychiatric aspects of physical disease****The sick role and illness behaviour**

PSYCHIATRIC ASPECTS OF PHYSICAL DISEASE

People with non-psychiatric, 'physical' diseases are more likely to suffer from psychiatric disorders than those who are well. The most common psychiatric disorders in physically unwell patients are mood or adjustment disorders and acute organic brain disorders (delirium). The relationship between psychological and physical symptoms may be understood in one of four ways:

- Psychological distress and disorders can precipitate physical diseases (e.g. the cardiac risk associated with depressive disorders or hypokalaemia causing arrhythmias in anorexia nervosa).
- Physical diseases and their treatments can cause psychological symptoms or ill-health (Table 23.6).
- Both the psychological and physical symptoms are caused by a common disease process (e.g. Huntington's chorea).
- Physical and psychological symptoms and disorders may be independently co-morbid, particularly in the elderly.

Factors that increase the risk of a psychiatric disorder in someone with a physical disease are shown in Table 23.7.

Differences in treatment

Although the basic principles are the same as in treating psychiatric illnesses in the physically healthy, there are some differences:

- **Uncertainty** regarding the physical diagnosis or prognosis, with its attendant tendency to imagine the worst, is often a triggering or maintaining factor, particularly in an adjustment or mood disorder. Good two-way communication between doctor and patient, with time taken to listen to the patient's concerns, is often the most effective 'antidepressant' available.
- The history may reveal the role of a **physical disease** or **treatment** exacerbating the psychiatric condition, which

should then be addressed (Table 23.6). For example, the dopamine agonist bromocriptine can precipitate a psychosis.

- When prescribing psychotropic drugs, the dose should be reduced in disorders affecting **pharmacokinetics**, e.g. fluoxetine in renal or hepatic failure.
- **Drug interactions** should be of particular concern, e.g. lithium and non-steroidal anti-inflammatory drugs.
- Sometimes a physical treatment may be planned that may **exacerbate** the psychiatric condition. An example would be high-dose steroids as part of chemotherapy in a patient with leukaemia and depressive illness.
- Always remember the risk of **suicide** in an inpatient with a mood disorder and take steps to reduce that risk; for example, moving the patient to a room on the ground floor and/or having a registered mental health nurse attend the patient while at risk.

THE SICK ROLE AND ILLNESS BEHAVIOUR

The **sick role** describes behaviour usually adopted by ill people. Such people are not expected to fulfil their normal social obligations. They are treated with sympathy by others and are only obliged to see their doctor and take medical advice or treatments.

Illness behaviour is the way in which given symptoms may be differentially perceived, evaluated and acted (or not acted) upon by different kinds of persons. We all have illness behaviour when we choose what to do about a symptom. Going to see a doctor is generally more likely with more severe, distressing and numerous symptoms. It is also more likely in introspective individuals who focus on their health.

Abnormal illness behaviour occurs when there is a discrepancy between the objective pathology present and the patient's response to it, in spite of adequate medical investigation and explanation.

FUNCTIONAL OR PSYCHOSOMATIC DISORDERS

So-called *functional* (in contrast to 'organic') disorders are illnesses in which there is no obvious pathology or anatomical change in an organ and there is a presumed dysfunction of an organ or system. Examples are given in Table 23.8. The psychiatric classification of these disorders would be *somatoform disorders*, but they do not fit easily within either medical or psychiatric classification systems, since they occupy the borderland between them. This classification also implies a dualistic 'mind or body' dichotomy, which is not supported by neuroscience. Since current classifications still support this outmoded understanding, this chapter will address these conditions in this way.

The word *psychosomatic* has had several meanings, including psychogenic, 'all in the mind', imaginary and malin-gering. The modern meaning is that psychosomatic disorders are syndromes in which both physical and psychological factors are likely to be causative. So-called medically unexplained symptoms and syndromes are very common in both primary care and the general hospital (over half the outpatients in gastroenterology and neurology clinics have these syndromes). Because orthodox medicine has not been particularly effective in treating or understanding these disorders, many patients perceive their doctors as unsympathetic and seek out complementary or even alternative treatments of uncertain efficacy.

Because epidemiological studies suggest that having one of these syndromes significantly increases the risk of having another, some doctors believe that these syndromes represent different manifestations of a single 'functional syndrome', indicating a global somatization process. Functional disorders also have a significant association with depressive and anxiety disorders. Against this view is the evidence that the majority of primary care people with most of these disorders do not have either a mood or other functional disorder. It also seems that it requires a major stress or the development of a co-morbid psychiatric disorder in order for such sufferers to see their doctor, which might explain why doctors are so impressed with the associations with both stress and psychiatric disorders. Doctors have historically tended to diagnose 'stress' or 'psychosomatic disorders' in people with symptoms that they cannot explain. History is full of such disorders being reclassified as research clarifies the pathology. An example is writer's cramp (p. 1122) which most neurologists now agree is a dystonia rather than a neurosis.

The likelihood is that these functional disorders will be reclassified as their causes and pathophysiology are revealed. Functional brain scans suggest enhancement of brain activity during *interoception* in more than one syndrome. Interoception is the perception of internal (visceral) phenomena, such as a rapid heartbeat.

Chronic fatigue syndrome (CFS)

There has probably been more controversy over the existence and cause of CFS than any other 'functional' syndrome in recent decades. This is reflected in its uncertain classification as *neurasthenia* in the psychiatric classification and *myalgic encephalomyelitis (ME)* under neurological diseases. There is now good evidence for the independent existence of this syndrome, although the diagnosis is made clinically and by exclusion of other fatiguing disorders. Its prevalence is 0.5–2.5% worldwide, mainly depending on how it is defined. It occurs most commonly in women between the ages of 20 and 50 years.

Clinical features

The cardinal symptom is chronic fatigue made worse by minimal exertion. The fatigue is usually both physical and mental, associated most commonly with:

- poor concentration
- impaired registration of memory
- alteration in sleep pattern (either insomnia or hypersomnia)
- muscular pain.

Mood disorders are present in a large minority of patients, and can cause problems in diagnosis because of the overlap in symptoms. These mood disorders may be secondary, independent (co-morbid), or primary (with a misdiagnosis of CFS).

Aetiology

Functional disorders often have some aetiological factors in common with each other (Table 23.9), as well as more specific aetiologies. For instance, CFS can be triggered by certain infections, such as infectious mononucleosis and viral hepatitis. About 10% of patients who have infectious mononucleosis have CFS 6 months after the onset of infection, yet there is no evidence of persistent infection in these patients. Those fatigue states which clearly do follow on a viral infection can also be classified as *post-viral fatigue syndromes*.

Other aetiological factors are uncertain. Immune and endocrine abnormalities noted in CFS may be secondary to the inactivity or sleep disturbance commonly seen. The role of stress is uncertain, with some indication that the influence of stress is mediated through consequent psychiatric disorders exacerbating fatigue, rather than any direct effect.

Management

The general principles of the management of functional disorders are given in Box 23.4. Specific management of CFS should include a mutually agreed and supervised programme of gradually increasing activity. However, only a quarter of patients recover after treatment. It is sometimes difficult to persuade a patient to accept what are inappropriately perceived as 'psychological therapies' for such a physically manifested condition. Antidepressants do not work in the absence of a mood disorder or insomnia.

Prognosis

Prognosis is poor without treatment, with less than 10% of hospital attenders recovered after 1 year. Outcomes are worse with greater severity, increasing age, co-morbid mood disorders, and the conviction that the illness is entirely physical. A large trial showed that about 60% improve with active rehabilitative treatments, such as graded exercise therapy and cognitive behaviour therapy when added to specialist medical care.

Table 23.9 Aetiological factors commonly seen in 'functional' disorders

Predisposing
Perfectionist, obsessional and introspective personality traits
Childhood traumas (physical and sexual abuse)
Similar illnesses in first-degree relatives
Precipitating (triggering)
Infections (chronic fatigue syndrome (CFS) and irritable bowel syndrome)
Traumatic events (especially accidents)
Physical problems ('fibromyalgia' and other chronic pain syndromes)
Life events that precipitate changed behaviours (e.g. going off sick)
Incidents where the patient believes others are responsible
Perpetuating (maintaining)
Inactivity with consequent physiological adaptation (CFS and 'fibromyalgia')
Avoidant behaviours – multiple chemical sensitivities (MCS), CFS
Maladaptive illness beliefs (that maintain maladaptive behaviours) (CFS, MCS)
Excessive dietary restrictions ('food allergies')
Stimulant drugs (e.g. caffeine)
Sleep disturbance
Mood disorders
Somatization disorder
Unresolved anger or guilt
Unresolved compensation claim

Fibromyalgia (chronic widespread pain, CWP)

This controversial condition of unknown aetiology overlaps with chronic fatigue syndrome, with both conditions causing fatigue and sleep disturbance (see p. 1162). Diffuse muscle and joint pains are more constant and severe in CWP, although the 'tender points', previously thought to be pathognomonic, are now known to be of no diagnostic importance (see p. 509.) Different specialists have different views.

CWP occurs most commonly in women aged 40–65 years, with a prevalence in the community of between 1% and 11%. There are associations with depressive and anxiety disorders, other functional disorders, physical deconditioning and a possibly characteristic sleep disturbance (Table 23.9). Functional brain scans suggest that patients actually perceive greater pain, supporting the idea of abnormal sensory processing, and this may be in part related to abnormalities in the regulation of central opioidergic mechanisms.

Management

Apart from the general principles in Box 23.4, management also consists of:

- symptomatic analgesia
- reversing the sleep disturbance
- a physically orientated rehabilitation programme.

A meta-analysis suggests that tricyclic antidepressants that inhibit reuptake of both serotonin (5-hydroxytryptamine – 5HT) and noradrenaline (norepinephrine) (e.g. amitriptyline, dosulepin) have the greatest effect on sleep, fatigue and pain. The doses used are too low for antidepressant effect and the drugs may work through their hypnotic and analgesic effects. Other centrally acting anti-nociceptive agents that are also antidepressants include duloxetine and milnacipran, used at full doses, or anticonvulsants, such as pregabalin and gabapentin.

Box 23.4 Management of functional somatic syndromes

The first principle is the identification and treatment of maintaining factors (e.g. dysfunctional beliefs and behaviours, mood and sleep disorders).

- Communication
 - Explanation of ill-health, including diagnosis and causes
 - Education about management (including self-help leaflets)
- Stopping drugs (e.g. caffeine causing insomnia, analgesics causing dependence)
- Rehabilitative therapies
 - Cognitive behaviour therapy (to challenge unhelpful beliefs and change coping strategies)
 - Supervised and graded exercise therapy for approximately 3 months (to reduce inactivity and improve fitness)
- Pharmacotherapies
 - Specific antidepressants for mood disorders, analgesia and sleep disturbance (e.g. 10–50 mg of amitriptyline at night for sleep and pain)
 - Symptomatic medicines (e.g. appropriate analgesia, taken only when necessary)

Other chronic pain syndromes

A chronic pain syndrome is a condition of chronic disabling pain for which no medical cause can be found. The psychiatric classification would be a persistent *somatoform pain disorder*, but this is unsatisfactory since the criteria include the stipulation that emotional factors must be the main cause, and it is clinically difficult to be that certain.

The main sites of chronic pain syndromes are the head, face, neck, lower back, abdomen, genitalia or all over (CWP, fibromyalgia). 'Functional' low back pain is the commonest 'physical' reason for being off sick long term in the UK (p. 503). Quite often, a minor abnormality will be found on investigation (such as mild cervical spondylosis on the neck X-ray), but this will not be severe enough to explain the severity of the pain and resultant disability. These pains are often unremitting and respond poorly to analgesics. Sleep disturbance is almost universal and co-morbid psychiatric disorders are commonly found.

Aetiology

The perception of pain involves sensory (nociceptive), emotional and cognitive processing in the brain. Functional brain scans suggest that the brain responds abnormally to pain in these conditions, with increased activation in response to chronic pain. This could be related to conditioned behavioural and physiological responses to the initial acute pain. The brain may then adapt to the prolonged stimulus of the pain by changing its central processing. The prefrontal cortex, thalamus and cingulate gyrus seem to be particularly affected and some of these areas are involved in the emotional appreciation of pain in general. Thus, it is possible to start to understand how beliefs, emotions and behaviours might influence the perception of chronic pain (Table 23.9).

Management

Management involves the same principles as used in other functional syndromes (Box 23.4). Since analgesics are rarely effective, and can cause long-term harm, patients should be encouraged to gradually reduce their use. It is often helpful to involve the patient's immediate family or partner, to ensure

that the partner is also supported and not unconsciously discouraging progress.

Specific drug treatments are few:

- **Nerve blocks** are not usually effective.
- **Anticonvulsants** such as carbamazepine, gabapentin and pregabalin may be given a therapeutic trial if the pain is thought to be neuropathic (see p. 1124).
- **Tricyclic antidepressants:** The antidepressant *dosulepin* is an effective treatment in half of the patients who have atypical facial pain, and this effect seems to be independent of dosulepin's effect on mood. Another tricyclic antidepressant, *amitriptyline*, is helpful in tension headaches, which might be related to its independent analgesic effect. Amitriptyline has the added bonus of increasing slow wave sleep, which may be why it is more effective than NSAIDs in chronic widespread pain.

Tricyclic antidepressants that affect both serotonin and noradrenaline (norepinephrine) reuptake (e.g. p. 1172) seem to be more effective than more selective noradrenaline reuptake inhibitors, e.g. in neuropathic pain. There is some evidence that tricyclics are generally superior to SSRIs in chronic pain syndromes.

Irritable bowel syndrome

This is one of the commonest functional syndromes, affecting some 10–30% of the population worldwide. The clinical features and management of the syndrome and the related functional bowel disorders are described in more detail in chapter 6. Although the majority of sufferers with the irritable bowel syndrome (IBS) do not have a psychiatric disorder, depressive illness should be excluded in people with constipation and a poor appetite. Anxiety disorders should be excluded in people with nausea and diarrhoea. Persistent abdominal pain or a feeling of emptiness may occasionally be the presenting symptom of a severe depressive illness, particularly in the elderly, with a *nihilistic delusion* that the body is empty or dead inside (see p. 1168).

Management

This is dealt with in more detail in Box 23.4. Seeing a physician who provides specific education that particularly addresses individual illness beliefs and concerns can provide lasting benefit. Psychological therapies that help the more severely affected include:

- cognitive behaviour therapy
- biofeedback
- hypnotherapy
- brief interpersonal psychotherapy.

If indicated, the choice of antidepressant should be determined by the effects of these drugs on bowel transit times, with tricyclic antidepressants normally slowing and selective serotonin reuptake inhibitors (SSRIs) (p. 1172) normally speeding up transit times.

Multiple chemical sensitivity, *Candida* hypersensitivity, and food allergies

Some complementary health practitioners, doctors and patients themselves make diagnoses of multiple chemical sensitivities (MCS) (e.g. to foods, smoking, perfumes, petrol), *Candida* hypersensitivity and allergies (to food, tap-water and even electricity). Symptoms and syndromes attributed to these putative disorders are numerous and variable and include all the functional disorders, *mood disorders* and *arthritis*. Scientific support for the existence of these

disorders is weak, particularly when double-blind methodologies have been used.

Type 1 hypersensitivities to foods such as nuts certainly exist, although they are fortunately uncommon (approximately 3/1000) (see pp. 68, 69). Direct *specific food intolerances* also occur (e.g. chocolate with migraine, caffeine with IBS).

Candidiasis can occur in the gastrointestinal tract in immunocompromised individuals, such as those with AIDS. Vaginal candidiasis can occur after antibiotic treatment in otherwise healthy women. A double-blind and controlled study of nystatin in women diagnosed as having candidiasis hypersensitivity syndrome showed that vaginitis was the only condition relieved more by nystatin than placebo. There is little evidence of *Candida* having a systemic role in other symptoms.

In spite of this evidence, the patient is often convinced of the legitimacy and usefulness of these diagnoses and their treatments.

Aetiology

Surveys of patients diagnosed with MCS or food allergies have shown high rates of current and previous mood and anxiety disorders (Table 23.9). Eating disorders (p. 1188) should be excluded in people with food intolerances. Some patients taking very low carbohydrate diets as putative treatments may develop reactive hypoglycaemia after a high carbohydrate meal, which they then interpret as a food allergy.

Classical conditioning can produce intolerance to foods and smells in healthy people and this may be a causative mechanism in some people with intolerance. This supports the existence of these intolerance conditions, but suggests they may be conditioned responses with attendant physiological consequences. This might explain why double-blinding sometimes abolishes the reaction to the stimulus.

Management

The general principles in Box 23.4 apply. If one assumes a phobic or conditioned response is responsible, graded exposure (systematic desensitization) to the conditioned stimulus may be worthwhile. Preliminary studies do suggest that this approach may successfully treat such intolerances, in the context of cognitive behaviour therapy.

Premenstrual syndrome

The premenstrual syndrome (PMS) consists of both physical and psychological symptoms that regularly occur during the premenstrual phase and substantially diminish or disappear soon after the period starts.

- Physical symptoms include headache, fatigue, breast tenderness, abdominal distension and fluid retention.
- Psychological symptoms can include irritability, emotional lability or low mood, and tension.

The *premenstrual (late luteal) dysphoric disorder (PMDD)* is a severe form of PMS with marked mood swings, irritability, depression and anxiety accompanying the physical symptoms. Women who generally suffer from mood disorders may be more prone to experience this disorder. The prevalence of PMS does not vary between cultures and is reported by the majority (75%) of women at some time in their lives. Severely disabling PMS (PMDD) occurs in about 3–8% of women.

The cause of the premenstrual syndrome remains unclear, although exacerbating factors include some of those outlined in Table 23.9. Research suggests that abnormalities of reproductive hormone receptors may play a role.

FURTHER READING

Ford AC, Talley NJ, Schoenfeld PS et al. Efficacy of antidepressants and psychological therapies in irritable bowel syndrome: systematic review and meta-analysis. *Gut* 2009; 58: 367–378.

Management

The general principles in Box 23.4 apply. Treatments with vitamin B₆ (p. 210), diuretics, progesterone, oral contraceptives, oil of evening primrose and oestrogen implants or patches (balanced by cyclical norethisterone) remain empirical. Psychotherapies aimed at enhancing the patient's coping skills can reduce disability. Two trials suggest that graded exercise therapy improves symptoms. Several studies have demonstrated that SSRIs (p. 1172) are effective treatments for the premenstrual dysphoric disorder.

The menopause

The clinical features and management of the menopause are described on page 973. A prospective study has shown that there is no increased incidence of depressive disorders at this time. Such a significant bodily change, sometimes occurring at the same time as children leaving home, is naturally accompanied by an emotional adjustment that does not normally amount to a pathological state.

SOMATOFORM DISORDERS

As explained in the section on functional disorders (p. 1162), the classification of somatoform disorders is unsatisfactory because of the uncertain nature and aetiology of these disorders. However, there are certain disorders, beyond those described in 'functional disorders', that present frequently and coherently enough to be usefully recognized.

Somatization disorder

One in 10 patients presenting with a functional disorder will fulfil the criteria of a chronic somatization disorder. The condition is composed of multiple, recurrent, medically unexplained physical symptoms, usually starting early in adult life. Symptoms may be referred to almost any part or bodily system. The patient has often had multiple medical opinions and repeated negative investigations. Medical reassurance that the symptoms do not have a demonstrable physical cause fails to reassure the patient, who will continue to 'doctor-shop'. The patient is usually reluctant to accept a psychological and/or social explanation for the symptoms. Abnormal illness behaviour is evident and patients can be attention-seeking and dependent on doctors. Yet they can complain about the medical care and attention they have previously received.

The aetiology is unknown, but both mood and personality disorders are often also present. It is often associated with dependence upon or misuse of prescribed medication, usually sedatives and analgesics. There is often a history of significant childhood traumas, or chronic ill-health in the child or parent, which may play an aetiological role or help to explain difficult therapeutic relationships (Table 23.9). The condition is probably the somatic presentation of psychological distress, although iatrogenic damage (from postoperative and drug-related problems) soon complicates the clinical picture. The course of the disorder is chronic and disabling, with long-standing family, marital and/or occupational problems.

Hypochondriasis

The conspicuous feature is a preoccupation with an assumed serious disease and its consequences. Patients commonly believe that they suffer from cancer or AIDS, or some other serious condition. Characteristically, such patients

repeatedly request laboratory and other investigations to either prove they are ill or reassure themselves that they are well. Such reassurance rarely lasts long before another cycle of worry and requests begins. The symptom of hypochondriasis may be secondary to or associated with a variety of psychiatric disorders, particularly depressive and anxiety disorders. Occasionally the hypochondriasis is delusional, secondary to schizophrenia or a depressive psychosis. Hypochondriasis may co-exist with physical disease but the diagnostic point is that the patient's concern is disproportionate and unjustified.

Management of somatoform disorders

The principles outlined in Box 23.4 apply to these disorders. Since they have a poor prognosis, the aim is to minimize disability. Furthermore, it is vital that all members of staff and close family members adopt the same approach to the patient's problems. The patients often consciously or unconsciously split both medical staff and family members into 'good' and 'bad' (or caring and uncaring) people, as a way of projecting their distress.

Patients appreciate a discussion and explanation of their symptoms. The doctor should sensitively explore possible psychological and social difficulties, if possible by demonstrating links between symptoms and stresses. Such discussion usually gives information that can be used to formulate an agreed plan of management. A contract of mutually agreed care involving the appropriate professionals (general practitioner, and a choice of psychotherapist, health psychologist, complementary health professional, physician or psychiatrist), with agreed frequency of visits and a review date, can be helpful in managing the condition. Management also includes cessation of reassurance that no serious disease has been uncovered, since this simply reinforces dependence on the doctor. Repeated laboratory investigations should be discouraged.

Cognitive behaviour therapy has been shown to provide effective rehabilitation in significant numbers of patients suffering from a somatoform disorder.

DISSOCIATIVE/CONVERSION DISORDERS

A dissociative disorder is a condition in which there is a profound loss of awareness or cognitive ability without medical explanation. The term dissociative indicates the disintegration of different mental activities, and covers such phenomena as amnesia, fugues and pseudoseizures (non-epileptic attacks).

Conversion disorder occurs when an unresolved conflict is converted into usually symbolic physical symptoms as a defence against it. Such symptoms commonly include paralysis, abnormal movements, sensory loss, aphonia, disorders of gait and pseudocyesis (false pregnancy). The lifetime prevalence has been estimated at 3–6 per 1000 in women, with a lower prevalence in men. Most cases begin before the age of 35 years. Dissociation is unusual in the elderly.

Clinical features

The various symptoms are usually divided into dissociative and conversion categories (Table 23.10). Dissociative disorders have the following three characteristics that are necessary in order to make the diagnosis:

- They occur in the absence of physical pathology that would fully explain the symptoms.

Somatoform disorders

Dissociative/conversion disorders

Table 23.10 Common dissociative/conversion symptoms

Dissociative (mental)	Conversion (physical)
Amnesia	Paralysis
Fugue	Disorders of gait
Pseudodementia	Tremor
Dissociative identity disorder	Aphonia
Psychosis	Mutism
	Sensory symptoms
	Globus hystericus
	Hysterical fits
	Blindness

- They are produced unconsciously.
 - Symptoms are not caused by overactivity of the sympathetic nervous system.
- Other characteristics include:
- Symptoms and signs often reflect a patient's ideas about illness.
 - There is usually abnormal illness behaviour, with exaggeration of disability.
 - There may have been significant childhood traumas.
 - **Primary gain** is the immediate relief from the emotional conflict.
 - **Secondary gain** refers to the social advantage gained by the patient by being ill and disabled (sympathy of family and friends, being off work, disability pension).
 - Physical disease is not uncommonly also present (e.g. pseudoseizures are more common in someone with epilepsy).

Dissociative amnesia commences suddenly. Patients are unable to recall long periods of their lives and may even deny any knowledge of their previous life or personal identity. In a *dissociative fugue*, patients not only lose their memory but wander away from their usual surroundings, and, when found, deny all memory of their whereabouts during this wandering. The differential diagnosis of a fugue state includes post-epileptic automatism, depressive illness and alcohol misuse.

Multiple personality disorder is rare, but dramatic, and may be triggered by suggestion on the part of a psychotherapist. There are rapid alterations between two or more 'personalities' in the same person, each of which is repressed and dissociated from the other 'personalities'. A differential diagnosis is rapid cycling manic depressive disorder which would explain sudden apparent changes in personality.

Differential diagnosis

Dissociation is usually a stable and reliable diagnosis over time, although high rates of co-morbid mood and personality disorders are found in chronic sufferers. Particular care should be taken to make the diagnosis on positive grounds, and not simply on the basis of an absence of a medical diagnosis. Care should also be taken to exclude or treat co-morbid psychiatric disorders.

Aetiology

Functional brain scans differ between healthy controls feigning a motor abnormality and people with a similar conversion motor symptom, which suggests that dissociation involves different areas of the brain from simulation (Fig. 23.1). Functional brain scanning of a patient with conversion paralysis has shown that recalling a past trauma not only activated the emotional areas, such as the amygdala, but also reduced motor cortex activity. This would suggest that conversion

Figure 23.1 Statistical parametric maps superimposed on an MRI scan of the anterior surface of the brain, orientated as though looking at a person head on. Red region shows hypofunction of people with conversion motor symptoms. The green region shows hypofunction of healthy controls feigning the same motor abnormality. (From Spence SA, Crimlisk HL, Cope H et al. Discrete neurophysiological correlates in prefrontal cortex during hysterical and feigned disorders of movement. *Lancet* 355:1243–1244, with permission.)

involves a disinhibition of voluntary will at an unconscious level, so that the patient can no longer *will* something to happen.

The psychoanalytical theory of dissociation is that it is the result of emotionally charged memories that are repressed into the unconscious at some point in the past. Symptoms are explained as the combined effects of repression and the symbolic conversion of this emotional energy into physical symptoms. This hypothesis is difficult to test, although there is some evidence that people with dissociative disorders are more likely to have suffered childhood abuse, particularly when the abuse was both sexual and physical and started early in childhood. Caution should be taken with such a history obtained by therapies that 'recover' childhood memories that were previously completely unknown to the patient.

People with dissociative disorders by definition adopt both the sick role and abnormal illness behaviour, with consequent secondary gains that help to maintain the illness.

Management

The treatment of dissociation is similar to the treatment of somatoform disorders in general, outlined above and in Box 23.4. The first task is to engage the patient and their family with an explanation of the illness that makes sense to them, is acceptable, and leads to the appropriate management. An invented example of a suitable explanation is given in Box 23.5. Such an explanation would be modified by mutual discussion until an agreed understanding was achieved, which would serve as a working model for the illness. Provision of a rehabilitation programme that addresses both the physical and psychological needs and problems of the patient would then be planned.

- A graded and mutually agreed plan for a return to normal function can usually be led by the appropriate therapist (e.g. speech therapist for dysphonia, physiotherapist for paralysis).

Box 23.5 An example of an explanation that might be given for a dissociative disorder

You told me about the tremendous shock you felt when your mother suddenly died. This was particularly the case since you hadn't spoken to her for so long beforehand, after that big disagreement with her over your wedding to John. You weren't able to say good-bye before she died. Your brain was overloaded with grief, guilt and anger all at once. I wonder whether that is why you aren't able to speak now. I wonder whether it's difficult to think of anything to say that would make things right, particularly since you can't speak with your mother now.

- At the same time, a psychotherapeutic assessment should be made in order to determine the appropriate form of psychotherapy. For instance, couple therapy will address a significant relationship difficulty; individual psychotherapy could ease an unresolved conflict from childhood.

Abreaction brought about by *hypnosis* or by intravenous injections of small amounts of midazolam may produce a dramatic, if sometimes short-lived, recovery. In the abreactive state, the patient is encouraged to relive the stressful events that provoked the disorder and to express the accompanying emotions, i.e. to abreact. Such an approach has been useful in the treatment of acute dissociative states in wartime, but appears to be of less value in civilian life. It should only be contemplated in the presence of an anaesthetist with suitable resuscitation equipment to hand.

Hypnotherapy is psychotherapy while the patient is in a hypnotic trance, the idea being that therapy is more possible because the patient is relaxed and not using repression. This may allow the therapist access to the previously unconscious emotional conflicts or memories. There are no published trials of this technique in dissociation, which Freud gave up as unsuccessful in order to found psychoanalysis, but some hypnotherapists claim good results. Care should be taken to avoid a catastrophic emotional reaction when the patient is suddenly faced with the previously repressed memories.

Prognosis

Most cases of recent onset recover quickly with treatment, which is why a positive diagnosis should be made early. Those cases that last longer than a year are likely to persist, with entrenched abnormal illness behaviour patterns. One study found that 83% were still unwell at 12 years' follow-up.

SLEEP DIFFICULTIES

Sleep is divided into rapid eye movement (REM) and non-REM sleep:

- As drowsiness begins, the alpha rhythm on an EEG disappears and is replaced by deepening *slow wave* activity (*non-REM*).
- After 60–90 minutes, this slow wave pattern is replaced by low amplitude waves on which are superimposed *rapid eye movements* lasting a few minutes.
- This cycle is repeated during the duration of sleep, with the REM periods becoming longer and the slow wave periods shorter and less deep (Fig. 23.2).

REM sleep is accompanied by dreaming and physiological arousal. Slow wave sleep is associated with release of anabolic hormones and cytokines, with an increased cellular mitotic rate. It helps to maintain host defences, metabolism

Figure 23.2 Sleep architecture, showing cycles of slow wave sleep interspersed with rapid eye movement (REM) sleep. Sleep is 'staged' by the electroencephalogram (EEG). Deeper sleep (stages 3 and 4) is demonstrated by slow waves on the EEG. Sleep occurs in cycles, light sleep (accompanied by REM sleep and dreaming) to deep sleep and back again, and these cycles last about 90 min.

Box 23.6 Common causes of insomnia

- Primary sleep disorders**
 - Periodic leg movements
 - Restless legs syndrome
- Secondary sleep disorders**
 - Psychiatric disorders:** Mood disorders (mania, depressive and anxiety disorders); delirium and dementia
 - Drug use or misuse:** Addictive drug withdrawal (alcohol, benzodiazepines); stimulant drugs (caffeine, amfetamines); prescribed drugs (steroids, dopamine agonists)
 - Physical conditions:** Pain (classically with carpal tunnel syndrome); nocturia (e.g. from prostatism); malnutrition

and repair of cells. For this reason slow wave sleep is increased in those conditions where growth or conservation is required (e.g. adolescence, pregnancy, thyrotoxicosis).

Insomnia is difficulty in sleeping; a third of adults complain of insomnia and in a third of these, it can be severe.

Primary sleep disorders include sleep apnoea (p. 818), narcolepsy which responds to tigotine, *the restless legs syndrome* (Ekblom's) (see p. 616) and the related *periodic leg movement disorder*, in which the legs (and sometimes the arms) jerk while asleep.

Delayed sleep phase syndrome occurs when the circadian pattern of sleep is delayed so that the patient sleeps from the early hours until mid-day or later, and is most common in young people. *Night terrors*, *sleep-walking* and *sleep-talking* are non-REM phenomena, called parasomnias, are most commonly found in children, but can recur in adults when under stress or suffering from a mood disorder. Sleep disorders secondary to another medical diagnosis will not be discussed here.

Psychophysiological insomnia commonly occurs secondary to functional, mood and substance misuse disorders, and when under stress (Box 23.6). It can often be triggered by one of these factors, but then become a habit on its own, driven by anticipation of insomnia and day-time naps.

Insomnia causes day-time sleepiness and fatigue, with consequences such as road traffic accidents. Assessment should pay particular attention to mood, life difficulties and drug intake (especially alcohol, nicotine and caffeine), and the timing of the insomnia should be ascertained:

- Initial insomnia** (trouble getting off to sleep) is common in mania, anxiety, depressive disorders and substance misuse.

Sleep difficulties

Wilson S, Nutt D. Assessment and management of insomnia. *Clin Med* 2005; 5:101–104.

- **Middle insomnia** (waking up in the middle of the night) occurs with medical conditions such as sleep apnoea and prostatism.
- **Late insomnia** (early morning waking) is caused by depressive illness and malnutrition (anorexia nervosa).

Habitual *alcohol* consumption should be carefully estimated since even a small excess can be a potent cause of insomnia, as well as recent withdrawal. *Caffeine* is perhaps the most commonly taken drug in the UK, and its effects are easily underestimated. Six cups of real coffee a day are likely to cause insomnia in the average healthy adult. Caffeine is not only found in tea and coffee, but is also found in chocolate, cola drinks and some analgesics. Prescription drugs that can either disturb sleep or cause vivid dreams include most appetite suppressants, glucocorticoids, dopamine agonists, lipid-soluble beta-blockers (e.g. propranolol) and certain psychotropic drugs (especially when first prescribed, e.g. fluoxetine, reboxetine, risperidone).

Hypersomnia is not uncommon in adolescents with depressive illness, occurs in narcolepsy, and may temporarily follow infections such as infectious mononucleosis.

Management of insomnia

This is determined by diagnosis. Where none is immediately apparent, it is worth educating the patient about sleep hygiene. In addition:

- Simple measures such as decreasing alcohol intake, having supper earlier, exercising daily, having a hot bath prior to going to bed and establishing a routine of going to bed at the same time should all be tried.
- Relaxation techniques and cognitive behaviour therapy have a role in those with intractable insomnia.
- Short half-life benzodiazepines can be useful for acute insomnia, but should not be used for more than 2 weeks continuously to avoid dependence.
- Non-benzodiazepine hypnotics (zaleplon, zopiclone, zolpidem) act at the benzodiazepine receptors and occasional dependence has been reported.
- Certain antihistamines (e.g. diphenhydramine and promethazine) and antidepressants (e.g. amitriptyline, trimipramine, trazodone, mirtazapine) are not addictive and can be used as hypnotics in low dose, with the added advantage of improving slow wave sleep. The commonest side-effects are morning sedation and weight gain.

MOOD (AFFECTIVE) DISORDERS

Classification

The central feature of these disorders is an abnormality of mood. Mood is best described in terms of a continuum ranging from severe depression at one extreme to severe mania at the other, with the normal, stable mood in the middle. Mood disorders are divided into bipolar and unipolar affective disorders.

Bipolar affective disorder

Patients suffer bouts of both depression and mania. Although mania can rarely occur by itself without depressive mood swings (thus being 'unipolar'), it is far more commonly found in association with depressive swings, even if sometimes it takes several years for the first depressive illness to appear.

- **Bipolar I** disorder is defined as one or more manic or mixed (signs of mania and depression) episodes.
- **Bipolar II** is defined as a depressive episode with at least one episode of hypomania (this is shorter lived than mania and is not accompanied by psychotic symptoms). Hypomania is noticeably abnormal but does not result in functional impairment or hospitalization.
- **Bipolar III** disorder is less well established and describes depressive episodes, with hypomania occurring only when taking an antidepressant.

About 10% of patients who have depressive illness are eventually found to have a bipolar illness.

Unipolar affective disorders

Patients suffer from depressive episodes alone, although they are commonly recurrent.

Depressive disorders

Depressive disorders or 'episodes' are classified by the ICD-10 as mild, moderate or severe, with or without somatic symptoms. Severe depressive episodes are divided according to the presence or absence of psychotic symptoms.

Clinical features of depressive disorder

Whereas everyone will at some time or other feel 'fed up' or 'down in the dumps', it is when such symptoms become qualitatively different, pervasive or interfere with normal functioning that a depressive illness has occurred. Depressive disorder, clinical or 'major' depression, is characterized by disturbances of mood, speech, energy and ideas (Table 23.11). Patients often describe their symptoms in physical terms. Marked fatigue and headache are the two most common physical symptoms in depressive illness and may be the first symptoms to appear. Patients describe the world as looking grey, themselves as lacking a zest for living, being devoid of pleasure and interest in life (anhedonia). Anxiety and panic attacks are common; secondary obsessional and phobic symptoms may emerge. Symptoms should last for at least 2 weeks and should cause significant incapacity (e.g. trouble working or relating to others) in order to be dealt with as an illness.

Table 23.11 Characteristic features of depressive illness

Characteristic	Clinical features
Mood	Depressed, miserable or irritable
Talk	Impoverished, slow, monotonous
Energy	Reduced, lethargic, lacking motivation
Ideas	Feelings of futility, guilt, self-reproach, unworthiness, hypochondriacal preoccupations, worrying, suicidal thoughts, delusions of guilt, nihilism and persecution
Cognition	Impaired learning, pseudodementia in elderly patients
Physical	Insomnia (especially early waking), poor appetite and weight loss, constipation, loss of libido, erectile dysfunction, bodily pains
Behaviour	Retardation or agitation, poverty of movement and expression
Hallucinations	Auditory – often hostile, critical

Box 23.7 Screening questions for depressive illness

- During the last month, have you often been bothered by feeling down, depressed or hopeless?
- During the last month, have you often been bothered by having little interest or pleasure in doing things?

If one or both of the answers is 'yes', assess further for depressive illness.

In the more severe forms, diurnal variation in mood can occur, feeling worse in the morning, after waking in the early hours with apprehension. Suicidal ideas are more frequent, intrusive and prolonged. Delusions of guilt, persecution and bodily disease are not uncommon, along with second-person auditory hallucinations insulting the patient or suggesting suicide. In severe depressive illness, particularly in the elderly, concentration and memory can be so badly affected that the patient appears to have dementia (pseudo-dementia). Delusions of poverty and non-existence (nihilism) occur particularly in this age group. Suicide is a real risk, with the lifetime risk being approximately 5% in primary care patients, but 15% in those with depressive illness severe enough to warrant admission to hospital. People with bipolar disorder are also at greater risk of suicide. Screening questions for depressive illness are shown in Box 23.7.

Epidemiology

About a third of the population will feel unhappy at any one time, but this is not the same as depressive illness; the middle-aged feel least happy compared to the young and elderly. The point prevalence of depressive illness is 5% in the community, with a further 3% having dysthymia (see below). It is more common in women, but there is no increase with age, and no difference by ethnic group or socioeconomic class (apart from a clear association with unemployment). Married and never married people have similar prevalence rates, with separated and divorced people having two to three times the prevalence. Some studies have suggested that depressive illness is becoming more common.

Depressive illnesses are more common in the presence of:

- physical diseases, particularly if chronic, stigmatizing or painful
- excessive and chronic alcohol use (probably the most depressing drug humans use)
- social stresses, particularly loss events, such as separation, redundancy and bereavement
- interpersonal difficulties with those close to the patient, especially when socially humiliated
- lack of social support, with no confiding relationship.

Depressed people with another physical disorder view themselves as more sick and disabled, visit their doctors almost four times as often as the non-depressed physically ill, stay in hospital longer, adhere less to medical advice and medication, and undergo more medical and surgical procedures. Depressive illness may be associated with increased mortality (excluding suicide) in people with physical illness, such as myocardial infarct.

Dysthymia

Dysthymia is a mild or moderate depressive illness that lasts intermittently for 2 years or more and is characterized by tiredness and low mood, lack of pleasure, low self-esteem and a feeling of discouragement. The mood relapses and

remits, with several weeks of feeling well, soon followed by longer periods of being unwell. It can be punctuated by depressive episodes of greater severity, so-called 'double depression'.

Seasonal affective disorder

Seasonal affective disorder is characterized by recurrent episodes of depressive illness occurring during the winter months in the northern hemisphere. Symptoms are similar to those found with atypical depressive illness, in that patients complain of hypersomnia, increased appetite (with carbohydrate craving) and weight gain, with profound fatigue. Such patients have a higher prevalence of bipolar affective disorder, and some doctors are uncertain whether the condition is different from normal depressive illness, with the accentuation of mood that naturally occurs by season. However, there is evidence that seasonal depressive illness can be successfully treated with bright light therapy given in the early morning, which causes a phase advance in the circadian rhythm of melatonin. In contrast, the same treatment given in the early evening, with consequent phase delay of melatonin secretion, is less antidepressant. Selective serotonin reuptake inhibitors (SSRIs) are alternative treatments

Puerperal affective disorders

Affective illnesses and distress are common in women soon after they have given birth.

'**Maternity blues**' describe the brief episodes of emotional lability, irritability and tearfulness that occur in about 50% of women 2–3 days postpartum and resolve spontaneously in a few days.

Postpartum psychosis occurs once in every 500–1000 births. Over 80% of cases are affective in type and the onset is usually within the first 2 weeks following delivery. In addition to the classical features of an affective psychosis, disorientation and confusion are often noted. Severely depressed patients may have delusional ideas that the child is deformed, evil or otherwise affected in some way, and such false ideas may lead to either attempts to kill the child or suicide. The response to speedy treatment is generally good. The recurrence rate for a psychosis in a subsequent puerperium is 20–30%.

Non-psychotic postnatal depressive disorders occur during the first postpartum year in 10% of mothers, especially in the first 3 months. Risk factors are first pregnancy, poor relationship with the partner, ambivalence about the pregnancy, and emotional personality traits. The Edinburgh Postnatal Depression Scale (EPDS) is a 10-item questionnaire and can be used as an effective screening tool. Depressive illness after childbirth is clinically similar to other depressive illnesses, but lack of emotional bonding with the baby is common.

Differential diagnosis

The differential diagnoses of depressive illness are shown in Table 23.12. Other psychiatric disorders are the most common misdiagnoses. Some 90% of patients presenting with a depressive illness while misusing alcohol will no longer be depressed 2 weeks after their last drink.

Pathological (abnormal) and normal grief are described on page 1180. Pathological grief is closely associated with depressive illness.

Investigations

A corroborative history can be valuable in helping to exclude differential diagnoses such as alcohol misuse and elucidating maintaining factors such as a poor relationship with a partner.

Mood (affective) disorders

FURTHER READING

Hickie IB, Ragers NL. Novel melatonin-based therapies. *Lancet* 2011; 378:621–631.

Table 23.12 Common differential diagnoses of depressive illness

Other psychiatric disorders
Alcohol misuse
Amphetamine (and derivatives) misuse and withdrawal
Borderline personality disorder
Dementia
Delirium
Schizophrenia
Normal and pathological grief
Organic (secondary) affective illness
Physical causes which are both necessary and sufficient as a cause
Cushing's syndrome
Thyroid disease (although sometimes depression persists after treatment)
Hyperparathyroidism
Corticosteroid treatment
Brain tumour (rarely without other neurological signs)

Physical investigations should be guided by the history and examination:

- They will often include measurement of free T₄ and TSH (particularly in women), calcium, sodium, potassium, mean corpuscular volume, γ -glutamyl transpeptidase, haemoglobin, white cell count, ESR or plasma viscosity
- Less commonly a chest X-ray, anti-nuclear antibody, morning and evening cortisol, electroencephalogram or a brain scan are indicated.

The aetiology of unipolar depressive disorders

The aetiology of unipolar depressive disorders is multifactorial and a mixture of genetic and environmental factors.

Genetic

Unipolar depression is probably polygenic, but no linkage has been firmly identified. The risk of unipolar depression in a first-degree relative of a patient is approximately three times the risk of the non-affected. The concordance of unipolar depression in monozygotic twins is between 30% and 60%, the concordance increasing with more recurrent illnesses. Polymorphisms that increase the risk of depression involve monoamines and their receptors, but studies are inconclusive. Serotonin transporter genes (5-HTTLPR) have provided a particular focus of interest in recent years, although a recent meta-analysis failed to demonstrate a putative gene-environment interaction with stressful life events and the subsequent development of a depressive episode. The issue is complicated by the genetic influence on sleep habits, emotional personality, and even life events, which are all involved in the genesis of depressive illness.

Neuroimaging changes

The use of functional magnetic resonance imaging (fMRI) and positron emission tomography (PET) has revealed a number of abnormalities in the brains of people with major depression. These changes are non-specific but involve regions that are associated with both the emotional and cognitive abnormalities seen in depression. Increased brain ventricle volume, orbitofrontal, dorsolateral frontal and anterior cingulate cortex altered activation have all been implicated. The hippocampus is smaller in several stress-related neuropsychiatric disorders, including recurrent depression.

Biochemical changes

Monoamines

The monoamine deficiency theory of depressive illness is supported by the efficacy of monoamine reuptake inhibitors and the depressive effect of dietary tryptophan depletion.

Neuroimaging studies have recently revealed a raised density of monoamine oxidase A (MAO-A) receptors. It is proposed that depression is related to a chronic and ongoing depletion of these neurotransmitters as a result of this enzyme's increased activity and its interaction with region-specific monoamine transporter densities. The relative transporter densities in particular regions and how they are affected by the global reduction in monoamine levels are then thought to determine the particular expression of the depressive illness and which symptoms predominate.

Neuroendocrine tests also suggest that the serotonin neurotransmitter system is downregulated. 5HT_{1A} and 5HT₂ receptor subtypes are thought most likely to be involved. Receptor-labelled functional brain scans suggest that dopamine underactivity is related to psychomotor retardation.

Hypothalamo-pituitary-adrenal axis

The administration of exogenous steroids is associated with the onset of depressive symptoms and people with Cushing's syndrome often demonstrate depressive episodes. Acute stress, whether physical or psychological, is associated with a rise in serum glucocorticoids. Severe depressive episodes have been associated with hypercortisolaemia (of note cortisol is low in 'atypical' depression with hyperphagia and hypersomnia). This cortisol dysregulation has been associated with impaired glucocorticoid negative feedback, adrenal hyper-responsiveness to ACTH and hypersecretion of CRH.

Exposure to the high levels of cortisol is thought to directly affect neuronal plasticity and lower resistance to neuronal damage. The hippocampus seems especially susceptible to this, resulting in atrophic changes. This in turn has further deleterious effects on wider neuroendocrine function, resulting in a self-perpetuating dysregulation that may serve to maintain and/or worsen the illness.

The interplay at this level becomes more complicated, with reduced central and peripheral glucocorticoid receptor sensitivity, hypothalamo-pituitary-adrenal (HPA) axis upregulation and the release of pro-inflammatory cytokines that may in turn explain changes in mood, fatigue, appetite, sensitivity to pain and libido (note that depression is a potentially dangerous side-effect of interferon treatment). Additionally at the cellular level, this affects monoamine transport, causes neuronal apoptosis and dysfunction of glial cells normally responsible for maintaining neuronal homeostasis.

Brain-derived neurotrophic factor

Healthy interactions between neurones and glial cells are maintained by brain-derived neurotrophic factor (BDNF), which is found in its greatest concentration in the hippocampus and cerebral cortex. It promotes cell growth and long-term potentiation (the enhancement of synchronous firing between two neurones). Pro-BDNF, its precursor, promotes the reduction of dendritic spines and apoptosis. BDNF is then involved in the growth and activity of neural networks.

- Animal studies show it is reduced under stressful conditions.
- Postmortem studies show reduced concentrations in suicide compared with non-suicide deaths.
- Adult humans with untreated depressive illness have three times lower concentrations when compared with

both healthy controls or those that have received antidepressant treatment.

- Low levels normalize with antidepressant treatment.

BDNF therefore has potential as an objective marker of depression and its response to treatment as well as being a potential target for treatment of the disorder itself.

Sleep

A reduced time between onset of sleep and REM sleep (shortened REM latency) and reduced slow wave sleep both occur in depressive illness. These abnormalities persist in some patients when they are not depressed. Families with several sufferers of depressive illness can share these traits, suggesting that sleep patterns may be inherited and predispose to depression.

Childhood traumas and personality

Physical, sexual and emotional abuse or neglect in childhood all predispose adults to depressive illness, but the effect is non-specific. Both 'neurotic' (emotional) and perfectionist personality traits are risks for depressive illness, and these may be determined as much by genetic factors as childhood environment.

Social factors

Some 30% of women will develop a depressive illness after a severe life event or difficulty, such as a divorce, and this is compounded by low self-esteem and a lack of a confiding relationship. Unemployment is a significant risk factor in men.

An integrated model of aetiology

Stress is more likely to trigger depressive illness in a person predisposed by lack of social support and/or certain personality traits. Stress in turn triggers various brain changes in both stress hormones (such as the release of corticotrophin-releasing hormone) and neurotransmitters (e.g. serotonin) that are both known to be altered in depressive illness. We can thus start to glimpse the model of an integrated biopsychosocial model of depressive illness. This model challenges dualistic ideas that depressive illnesses are either psychological or physical; depressive illnesses involve both the mind and the body, which are themselves indivisible.

Treatment of depressive illness

The patient needs to know the diagnosis to provide understanding and rationalization of the overwhelming distress inherent in depressive illness. Knowing that self-loathing, guilt and suicidal thoughts are caused by the illness may have an 'antidepressant' effect. The further treatment of depressive disorders involves physical, psychological and social interventions (Box 23.8).

Patients who are actively suicidal, severely depressed (with or without psychotic symptoms) should be admitted to hospital. Admission is necessary for perhaps 1 in 1000 people with clinical depression in primary care. This provides the patient a break from self-care, and allows support, listening, observation, the close monitoring of treatments and the prevention of suicide. Avoid the pitfall of not treating a depressive illness just because it seems an 'understandable' reaction to serious illness or difficult circumstances. This is particularly likely to happen if the patient is elderly, severely or even terminally ill.

Exercise

There is good evidence that regular exercise, particularly involving other people, can help relieve depressive illness of

Box 23.8 Management of depressive illness

Physical

- Stop depressing drugs (alcohol, steroids)
- Regular exercise (good for mild to moderate depression)
- Antidepressants (choice determined by side-effects, co-morbid illnesses and interactions)
- Adjunctive drugs (e.g. lithium; if no response to two different antidepressants)
- Electroconvulsive therapy (ECT) (if life-threatening or non-responsive)

Psychological

- Education and regular follow-up by same professional
- Cognitive behaviour therapy (CBT)
- Other indicated psychotherapies (couple, family, interpersonal)

Social

- Financial: eligible benefits, debt counselling
- Employment: acquire or change job or career
- Housing: adequate, secure tenancy, safe, social neighbours
- Young children: child-care support

Treatments combined

- The most effective treatment is a mixture of CBT and an antidepressant

mild or moderate severity. The benefit is independent of a physical training effect.

Drugs used in the treatment of clinical depression

Today's antidepressants are designed to provide an acute increase in monoamine activity. They do this either through preventing reuptake or enzymatic degradation. Note that this occurs acutely and that although an equally rapid depletion of monoamines has an acute mood lowering effect, the mood elevating benefits of these drugs require weeks of continuous administration. The benefits are therefore unlikely to be due to this mechanism alone.

The effects of chronic administration of monoamine reuptake inhibitors are various. Examples include an increase in the synthesis of binding proteins necessary for serotonin receptor activity and increases in cyclic AMP activation which in turn increases BDNF synthesis, enhances glucocorticoid receptor sensitivity and inhibits cytokine signalling. These may be secondary to the acute restoration of monoamine levels but rely upon transcriptional and translational changes that alter neuronal plasticity. It is this protein synthesis-dependent process that is currently thought to be the final pathway responsible for the clinical effect of the drugs.

As the neurobiology for depressive illness becomes clearer, so too are novel approaches to its treatment; some of the novel targets under active investigation are listed in Box 23.9.

Box 23.9 Potential targets for novel antidepressant agents

Brain-derived neurotrophic factor (BDNF)	Alpha-melanocyte stimulating hormone
Tumour necrosis factor- α (TNF- α)	Ghrelin
Interleukin-1 beta (IL-1 β)	Leptin
Glucocorticoid receptors	Orexins
Corticotrophin-releasing hormone	Neuropeptide Y
Melanin concentrating hormone	Nesfatin-1

General approach to drug treatment of depression

- Recreational drugs such as alcohol should be stopped. Prescribed medicines suspected of exacerbating depression, such as corticosteroids, should be gradually stopped or reduced to a safe minimum.
- Treatment with antidepressants is more successful when accompanied by sufficient patient education and regular follow-up, particularly a week after starting treatment and throughout the following 6 weeks. Dysthymia responds less well to antidepressants than does a depressive episode.
- The commonest two pharmacological types of antidepressants are *selective serotonin reuptake inhibitors (SSRIs)* and *tricyclic antidepressants (TCAs)*. All antidepressants have similar efficacy and speed of onset. Choice depends on their side-effects, which can be used to positive effect (sedating drugs given at night to enhance sleep), and their safety. A course of antidepressants should be given until 6 months after recovery from a first episode to prevent relapse. Stopping antidepressants immediately upon recovery leads to a 50% relapse rate within 6 months. The two greatest problems with these drugs are persuading the patient to take them and adherence, since 80% of the UK public wrongly believe that they are addictive.

Drug choices in specific circumstances

- **Recurrent episodes:** maintenance treatment with the antidepressant at the dose that obtained remission should be continued for at least 2 years. Maintenance treatment beyond this point should be re-evaluated, taking into account age, co-morbidities and risk factors.
- **Refractory depressive illness:** whilst 50% may show response, as few as 30% of individuals (outpatients) get a complete remission with the first choice of antidepressant agent. Strategies available at this point are switching drug classes or augmentation with other agents. This should be overseen by a specialist.
- **Psychotic depression** needs either a combination of an antidepressant and an antipsychotic drug or electroconvulsive therapy.
- **Bipolar depressive illness:** monotherapy with quetiapine has been proposed as the drug of choice. Other drugs include mood stabilizers or olanzapine, either alone or in combination with an antidepressant (see p. 1176).

Selective serotonin reuptake inhibitors (SSRIs)

SSRIs selectively inhibit the reuptake of the monoamine serotonin (5HT) within the synapse, and are thus termed 'selective serotonin reuptake inhibitors' or SSRIs. Citalopram and its laevo isomer escitalopram, fluvoxamine, fluoxetine, paroxetine and sertraline have the advantage of causing less serious or disabling side-effects than tricyclics. For instance, SSRIs do not usually cause significant weight gain. Because of their long half-lives they can also be given just once a day, normally in the morning after breakfast. For these reasons patients adhere more to treatment and therefore SSRIs are now first-line treatments for depressive disorders. Vilazodone is a recently introduced SSRI and serotonin 1A receptor partial agonist. It also has partial agonist effects and does not cause weight gain.

The most common side-effects of SSRIs resemble a 'hangover' and include nausea, vomiting, headache,

diarrhoea and dry mouth. Insomnia and paradoxical agitation can occur when first starting the drugs. Adolescents, in particular, may develop suicidal thoughts with SSRIs; only fluoxetine is licensed in the UK for adolescents for this reason. Further studies suggest that this is a small risk, if present, and no study has shown a significant increased risk of suicide itself. One in five patients also has sexual side-effects, such as erectile dysfunction and loss of libido. Uncommon side-effects include restless legs syndrome (see p. 616) and hyponatraemia.

A risk of bleeding is associated with SSRIs and is thought to be due to the inhibition of serotonin uptake by platelets as part of normal aggregation in response to vascular injury. To date, much of the reported incidence relates to gastrointestinal bleeding and any patient with one or more risk factors for upper gastrointestinal bleeding, such as taking a non-steroidal anti-inflammatory, should be given gastro-protection with a proton pump inhibitor. A risk of intra- and postoperative bleeding has also been reported. Whilst antidepressants are certainly not a reason to withhold a surgical intervention, it is certainly an added risk of which the surgeon and anaesthetist should be aware.

'Serotonin syndrome'. This is a toxic hyperserotonergic state, which can be caused by the ingestion of two or more drugs that increase serotonin levels, e.g. an SSRI combined with a monoamine oxidase inhibitor (MAOI), dopaminergic drugs (e.g. selegiline) or a tricyclic antidepressant. Symptoms include agitation, confusion, tremor, diarrhoea, tachycardia and hypertension; hyperthermia is characteristic. This is a potential medical emergency and treatment needs to begin with admission to hospital under a medical team.

Discontinuity syndrome, a specific withdrawal syndrome, has also been reported with SSRIs. This is characterized by shivering, anxiety, dizziness, 'electric shocks', headache and nausea. Patients should be warned not to omit a dose and to gradually reduce SSRIs when stopping them. All antidepressants have the potential to cause a discontinuity syndrome if suddenly stopped.

Tricyclic antidepressants (TCAs)

These drugs potentiate the action of the monoamines, noradrenaline (norepinephrine) and serotonin, by inhibiting their reuptake into nerve terminals (Fig. 23.3). Other tricyclics in common use include nortriptyline, doxepin and clomipramine. Dosulepin, imipramine and amitriptyline are the three most commonly used in the UK, but many related compounds have been introduced, some having fewer autonomic and cardiotoxic effects (e.g. lofepramine).

TCAs have a number of side-effects (Table 23.13). In long-term treatment or prophylaxis, weight gain is most troublesome. Because of their toxicity in overdose, it is wisest not to prescribe them to outpatients who have suicidal thoughts without monitoring or giving the drugs to a reliable family member to look after.

Trazodone is different from other tricyclic antidepressants and acts by blockade of 5HT₂ receptors.

SNRIs and NRIs

These antidepressants block a number of different neurotransmitter receptors both at the synapse and elsewhere. Their different receptor profiles cause different side-effects.

- **SNRIs:** *venlafaxine* is a potent blocker of both *serotonin* and *noradrenaline (norepinephrine) reuptake (SNRI)*. It has negligible affinity for other neurotransmitter receptor sites and so produces less sedation and fewer antimuscarinic effects. It can be given in slow-release

Figure 23.3 The effect of drugs used in the treatment of depression on CNS serotonergic and adrenergic functioning. The majority of released serotonin and noradrenaline is rapidly removed from the synapse by reuptake into the neurone (yellow circles). There is a range of antidepressants, which vary in their abilities to inhibit the reuptake of serotonin or noradrenaline, thus enhancing the synapse concentrations of these transmitters. Stimulation of presynaptic α_2 -adrenoceptors reduces monoamine release; mirtazapine blocks these presynaptic autoreceptors, and increases the release and transmission of noradrenaline and serotonin. Other drugs act by significantly blocking postsynaptic receptors which are upregulated in depression. MAO, monoamine oxidase; NA, noradrenaline; NRI, (selective) noradrenaline reuptake inhibitor; SNRI, serotonin and noradrenaline reuptake inhibitor; SSRI, selective serotonin reuptake inhibitor; TCA, 'classic' tricyclic antidepressant. (From Waller DG, Renwick A, Hillier K, eds. *Medical Pharmacology and Therapeutics*, Edinburgh: Saunders; 2010, with permission.)

Table 23.13 Side-effects of tricyclic antidepressants

Antimuscarinic effects	Convulsant activity
Dry mouth Constipation Tremor Blurred vision Urinary retention	Lowered seizure threshold
	Other effects
	Weight gain Sedation Mania (rarely)
Cardiovascular	
QT prolongation Arrhythmias Postural hypotension	

form with the advantage of once-daily dosage. Nausea is the commonest side-effect and patients should be monitored for hypertension. It should not be prescribed in those with either uncontrolled hypertension or in those prone to cardiac arrhythmias; if an arrhythmia

is suspected, it should be ruled out by ECG before starting treatment. *Duloxetine* works in a similar way to venlafaxine and has been found especially helpful with chronic pain.

- **NSSA:** *mirtazapine* is a $5HT_2$ and $5HT_3$ receptor antagonist and a potent α_2 -adrenergic blocker. The consequent effect is to increase both *noradrenaline* (norepinephrine) and *selective serotonin transmission: an NSSA*. It can be given at night to aid sleep and rarely causes sexual side-effects. Mirtazapine can be sedating in low dose and can cause weight gain. An uncommon adverse effect is agranulocytosis.

Monoamine oxidase inhibitors (MAOIs)

These act by irreversibly inhibiting the intracellular enzymes monoamine oxidase A and B, leading to an increase of noradrenaline (norepinephrine), dopamine and 5HT in the brain (see Fig. 23.3). Because of their side-effects and restrictions while taking them, they are rarely used by non-psychiatrists. MAOIs also produce a dangerous hypertensive reaction with foods containing tyramine or dopamine and therefore a restricted diet is prescribed. Tyramine is present in cheese, pickled herrings, yeast extracts, certain red wines, and any food, such as game, that has undergone partial decomposition. Dopamine is present in broad beans. MAOIs interact with drugs such as pethidine and can also occasionally cause liver damage.

Reversible inhibitors of monoamine oxidase A (RIMAs)

An example is moclobemide; usual dose 300 mg daily. These drugs appear to have fewer side-effects than the MAOIs (insomnia and headache, but some sexual problems) and constitute a low risk in overdose. Patients prescribed such antidepressants should be told that they can eat a normal diet, but should be careful to avoid excessive amounts of food rich in tyramine (see above).

Antidepressant augmentation

If two trials of antidepressants have failed, adding a second concomitant drug, e.g. lithium or tri-iodothyronine, can sometimes be helpful.

Antidepressant use in general medicine

- **Cardiac disease.** In people with cardiac disease, SSRIs, lofepramine and trazodone are preferred over more quinidine-like compounds.
- **Epilepsy.** MAOIs and mirtazapine do not affect epileptic thresholds.
- **Drug interactions.** SSRIs are metabolized by the cytochrome P450 system, unlike venlafaxine, mirtazapine and reboxetine; the latter therefore have fewer drug interactions.
- **Herbal medicine.** Care should be taken not to prescribe antidepressants while a patient is taking the herbal antidepressant St John's wort, which interacts with serotonergic drugs in particular.
- **Elderly.** Doses of antidepressants should initially be halved in the elderly and in people with renal or hepatic failure.
- **Pregnancy.** Antidepressants should be avoided if possible in pregnancy and breast-feeding. If other treatments are ineffective, the risks of drug therapy should be balanced against taking no treatment, since depression can affect fetal progress and future mother-child bonding. Tricyclic antidepressants are generally

1329–1332.

believed to be safe in pregnancy, with no significant increase in congenital malformations in fetuses exposed to them. However, occasionally their antimuscarinic side-effects produce jitteriness, sucking problems and hyperexcitability in the newborn. Postpartum plasma levels of babies breast-fed by treated mothers are negligible. SSRIs do not seem to be teratogenic but manufacturers advise against their use in pregnancy until more data are available. Pulmonary hypertension in the newborn is a rare complication. MAOIs should be avoided during pregnancy because of the possibility of a hypertensive reaction in the mother.

Electroconvulsive therapy (ECT)

ECT is the treatment of choice in severe life-threatening depressive illness, particularly when psychotic symptoms are present. It is sometimes essential treatment when the patient is dangerously suicidal or refusing to eat and drink and when a rapid resolution is required such as in postpartum depressive illness, when returning baby to mother as soon as it is safe so to do forms part of the treatment.

The treatment is performed under general anaesthetic and involves the passage of an electric current across two electrodes applied to the anterior temporal areas of the scalp, in order to induce an epileptic fit. It was previously believed that the extent of the generalized seizure was proportional to its efficacy. We now know that the motoric seizure is less significant than its electrophysiological evidence (spike and wave activity on an EEG), without which benefit is unlikely to be seen. Treatments are normally given twice a week for 3–6 weeks.

ECT is a controversial treatment, yet it is free of serious side-effects. Most side-effects are due to the general anaesthetic; post-ictal confusion and headache are not uncommon, transient and short-term retrograde amnesia and a temporary defect in new learning can occur during the weeks of treatment, but these are typically short-lived effects. The frequency with which defects in autobiographical memory occur during the time of treatment should be noted. These are discrete and in most instances not recognized by the patient, unless the particular memory is actively sought. It is necessary to warn patients of its possibility beforehand.

Uncommonly used treatments

Transcranial magnetic stimulation (TMS) shows moderate efficacy, but is uncommonly used. *Psychosurgery* is very occasionally considered in people with severe intractable depressive illness, when all other treatments have failed (see p. 1181). A third improve remarkably, while a further third improve somewhat.

Vagal nerve and deep brain stimulation may represent major advances in the management of chronic and treatment-refractory depressive disorders, but definitive trials are not available.

Psychological treatments**Cognitive behaviour therapy (CBT)**

Beck developed CBT to reverse the negative cognitive triad with which patients regarded themselves, their situation and their futures. It involves the identification of the negative automatic thoughts that maintain the negative perceptions that feed depression. They commonly include: catastrophizing (e.g. making a 'mountain out of a mole-hill'); overgeneralizing (e.g. 'I failed an exam; therefore I am a failure as a person.');

categorical ('black or white') thinking (e.g. 'My work is either perfect or abysmal.'). CBT then involves identifying the links between these thoughts, consequent behaviour,

and feeling low, and then testing their logic. This is done by looking at the evidence either in the therapy sessions (e.g. Q: 'Did you pass the other exams you took?'; A: 'Yes; I guess I did.')

or by behavioural 'experiments' (e.g. showing the 'abysmal' work to a colleague and asking their opinion).

There is good evidence that individual CBT is as effective as antidepressant drugs for mild and moderate depressive illness. CBT is also effective in preventing a relapse of clinical depression. Individual CBT is more effective than group delivered therapy, and there is preliminary evidence that computer delivered CBT programmes are also helpful, when used to supplement therapist involvement. Mindfulness-based CBT, based on the use of meditation, can play a helpful role in prevention of recurrence.

Interpersonal psychotherapy

This psychotherapy is probably as effective as both antidepressants and CBT in mild and moderate clinical depression. The therapist focuses on a patient's interpersonal relationships involved in, or affected by, their illness (especially relationship changes or deficiencies), using problem-solving techniques to help the patient to find solutions.

Other psychotherapies

Couple therapy is particularly effective when a patient is in a problematic relationship that may be contributing to the perpetuation of the depressive illness; both the patient and partner attend therapy.

Family therapy is effective not only in a family with problems, but also as a way of helping the family to help the patient get better. It may involve understanding one family member's 'depression' as a systemic 'solution' for a wider problem within the family.

Social treatments

Many people with clinical depression have associated social problems (Box 23.8). Assistance with social problems can make a significant contribution to clinical recovery. Other social interventions include the provision of group support, social clubs, occupational therapy and referral to a social worker. Educational programmes, self-help groups, and informed and supportive family members can help improve outcome.

Prognosis

Depression is one of the leading causes of disease burden worldwide. People with major depressive illness are between 1.5 and 2 times more likely to die than non-depressed people in the next 16 years, and the risks are not only suicide, but also cardiovascular. Depression produces greater disability than angina, arthritis, asthma and diabetes, which makes effective treatment and prevention imperative.

The majority of patients have recovered by 6 months in primary care and 12 months in secondary care. About a quarter of patients attending hospital with depressive illnesses will have a recurrence within 1 year, and three-quarters will have a recurrence within 10 years. People with recurrent depressive illnesses should be offered prevention. This may involve CBT that concentrates on relapse prevention, other forms of psychotherapy, antidepressant medication and advice on lifestyle activities such as regular exercise. Full-dose antidepressants are the most effective prophylaxis in recurrent depressive disorders.

Mania, hypomania and bipolar disorder

Mania and hypomania almost always occur as part of a *bipolar disorder*. The clinical features of mania include a

Table 23.14 Clinical features of mania

Characteristic	Clinical feature
Mood	Elevated or irritable
Talk	Fast, pressurized, flight of ideas
Energy	Excessive
Ideas	Grandiose, self-confident, delusions of wealth, power, influence or of religious significance, sometimes persecutory
Cognition	Disturbance of registration of memories
Physical	Insomnia, mild to moderate weight loss, increased libido
Behaviour	Disinhibition, increased sexual activity, excessive drinking or spending
Hallucinations	Fleeting auditory

marked elevation of mood, characterized by euphoria, over-activity and disinhibition (Table 23.14). Hypomania is the mild form of mania. Hypomania lasts a shorter time and is less severe, with no psychotic features and less disability. Hypomania can be distinguished from normal happiness by its persistence, non-reactivity (not provoked by good news and not affected by bad news) and social disability.

The social disability of mania can be severe, with disinhibited behaviour leading to significant debts (from overspending), lost relationships (from promiscuity or irritability), social ostracism and lost employment (from reckless or disinhibited behaviour).

Some patients have a *rapid cycling* illness, with frequent swings from one mood state to another. A *mixed affective state* occurs when features of mania and depressive illness are seen in the same episode. *Cyclothymia* is a personality trait with spontaneous swings in mood not sufficiently severe or persistent to warrant another diagnosis.

Differential diagnosis

Acute intoxication with recreational drugs such as amfetamines, amphetamine derivatives (MDMA: Ecstasy), and cocaine can mimic mania. Up to a quarter of people with Cushing's syndrome develop mania. Similarly corticosteroids can induce mania less commonly than depressive illness. Dopamine agonists (e.g. bromocriptine) are also known to sometimes induce mania.

Epidemiology

The lifetime prevalence of bipolar affective disorder is 1% across the world. Unlike unipolar depressive illness, it is equally common in men and women, supporting its different aetiology. There is no variation by socioeconomic class or race. The mean age of onset is 21; earlier than unipolar depression. The higher prevalence found in divorced people is probably a consequence of the condition.

Aetiology

Genetic

There is strong evidence for a genetic aetiology in this disorder. There is a 60–80% concordance rate in monozygotic twins, compared to 15% in dizygotic twins, suggesting a high rate of heritability. Adoption studies show similar rates, so this high rate is probably genetic and not due to the family environment. Linkage studies have so far proved disappointing, with several polymorphism associations being

Table 23.15 Treatment options for the management of acute mania or hypomania

Choice of agent is determined largely by clinical judgement, contraindications and prior response	
Stop antidepressant medication	
If the patient is NOT on antimanic medication, then start:	If the patient is already ON antimanic medication:
Antipsychotic, e.g. aripiprazole 15 mg daily Or Valproate 750 mg daily Or Lithium 0.4 mg daily to serum lithium of 0.4–1.0 mmol/L If response is inadequate: Antipsychotic + valproate or lithium	If taking an antipsychotic: Check dose and compliance. Increase if possible or add valproate or lithium If taking valproate: Check plasma levels and increase dose aiming for a serum concentration of 125 mg/L as tolerated and/or add an antipsychotic (this should be done if mania is severe) If taking lithium: Check plasma levels and increase the dose to gain a level of 1.0–1.2 mmol/L if necessary (Note: higher than usual reference range) or add an antipsychotic (this should be done if mania is severe) If taking carbamazepine: add an antipsychotic if appropriate
A short-acting benzodiazepine may be added to assist with agitation in all patients	

found, and a recent large study finding similar polymorphisms to those associated with schizophrenia.

Biochemical

Brain monoamines, e.g. serotonin, seem to be increased in mania. Dexamethasone tends not to suppress cortisol levels in people with mania, suggesting a similar pattern of non-suppression to that seen in severe depressive illness.

Psychological

The effect of life events is much weaker in bipolar compared with unipolar illnesses; most effect being apparent at first onset. Similarly, personality does not seem to be a major influence, in contrast to unipolar depression, although there is some evidence of a link with the creativity and divergent thinking that is an advantage in the right occupation

Treatment

Acute mania or hypomania

This is summarized in Table 23.15.

- Acute mania is treated with an atypical antipsychotic (neuroleptic), sodium valproate or lithium. The atypical antipsychotics aripiprazole, olanzapine, quetiapine and risperidone are particularly recommended, especially with behavioural disturbance. Doses are similar to those used in schizophrenia. The behavioural excitement and overactivity are usually reduced within days, but elation, grandiosity and associated delusions often take longer to respond.
- Lithium may be used in instances where compliance is likely to be good; however, the screening necessary

FURTHER READING

Cipriani A et al. Comparative efficacy and acceptability of antimanic drugs in acute mania. *Lancet* 2011; 378:1306–1315.

prior to its use (see below) may prohibit its use in these circumstances as a first-line agent.

- Valproic acid is also helpful in hypomania or in rapidly cycling illnesses (see below).

Prevention in bipolar disorders

Since bipolar illnesses tend to be relapsing and remitting, prevention of recurrence is the major therapeutic challenge in management. A patient who has experienced more than two episodes of affective disorder within a 5-year period is likely to benefit from preventive treatments. Recommendations include lithium, olanzapine, and valproic acid (so long as the patient is not a woman at risk of pregnancy).

Lithium

Lithium (carbonate or citrate) is one of the two main agents used for prophylaxis in people with repeated episodes of bipolar illness (the other being valproic acid). It is rapidly absorbed from the gastrointestinal tract and more than 95% is excreted by the kidneys; small amounts are found in the saliva, sweat and breast milk. Renal clearance of lithium correlates with renal creatinine clearance. Lithium is a mood-stabilizing drug that prevents mania more than depression. It reduces the frequency and severity of relapses by half and significantly reduces the likelihood of suicide. Its mode of action is unknown, but lithium is known to act on the serotonergic system. Poor response to lithium is associated with a negative family history, an unstable premorbid personality, and a rapid cycling illness. Recent pharmacogenetic work suggests that certain polymorphisms may predict response.

Plasma levels. These should be monitored weekly, with blood drawn 12 h after the last dose (a 'trough' level) until a steady state is reached and at 3-monthly intervals thereafter. The minimum level for prophylaxis is 0.4 mmol/L, with an optimum range of between 0.6 and 0.75 mmol. Levels higher than this may afford further protection against manic episodes but the relationship with depression is less clear. For this reason, the therapeutic range is typically quoted as 0.5–1.0 mmol/L. Fluctuations in plasma levels increase the risk of relapse.

Screening prior to starting lithium and at 6-monthly intervals thereafter includes:

- **Thyroid function** (free T₄, TSH and thyroid autoantibodies). Lithium interferes with thyroid function and can produce frank hypothyroidism. The presence of thyroid autoantibodies increases the risk.
- **Parathyroid function.** Serum calcium and parathyroid hormone levels higher in 10% of patients.
- **Renal function** (serum urea and creatinine, estimated glomerular filtration rate and 24-hour urinary volume). Long-term treatment with lithium causes two renal problems: nephrogenic diabetes insipidus (DI) and reduced glomerular function (see p. 566). The best screen for DI is to ask the patient about polyuria and polydipsia.

Toxicity. Patients should carry a lithium card with them at all times, be advised to avoid dehydration, and be warned of drug interactions, such as with NSAIDs and diuretics. As with all medications, it is vital to discuss side-effects and signs of toxicity (these are listed in Box. 23.10).

Pregnancy. As a rule, lithium is not advised during pregnancy, particularly in the 1st trimester, because of an increased risk of fetal malformation (Ebstein's anomaly). Between 25% and 30% of women with a history of bipolar disorder relapse within 2 weeks of delivery. Restarting lithium within 24 h of delivery (if the mother is prepared to forgo breast-feeding) markedly reduces the risk of relapse.

Box 23.10 Lithium

Side-effects

Nausea	Polyuria	} due to nephrogenic diabetes insipidus
Diarrhoea	Polydipsia	
Fine tremor	Weight gain, mainly through increased appetite	

Toxicity (>1.5 mmol/L, more likely with dehydration and drug interactions)

Drowsiness	Dysarthria
Nausea	Delirium
Vomiting	Convulsions
Blurred vision	Coma
Coarse tremor	Death
Ataxia	

Other mood stabilizers

Valproic acid (as the semisodium salt) is recommended both in prophylaxis and treatment of manic states. Second-line treatments include *carbamazepine* and *lamotrigine*. Some patients who do not respond to lithium may respond to these anticonvulsants or a combination of both. People with rapid cycling illnesses show a better response to anticonvulsants than to lithium. For antimanic treatment, dosage in the initial stage of treatment will be 200 mg twice daily of carbamazepine, increasing to a normal dose of 800–1000 mg.

Other drugs which appear to exercise a prophylactic mood-stabilizing effect include *olanzapine* and *risperidone*.

Both carbamazepine and valproate can be teratogenic (neural tube defects) and should be avoided in pregnancy. Other side-effects of these drugs are given in Chapter 22.

Prognosis

The average duration of a manic episode is 2 months, with 95% making a full recovery in time. Recurrence is the rule in bipolar disorders, with up to 90% relapsing within 10 years.

SUICIDE AND SELF-HARM

(see also p. 909)

Suicide accounts for 2% of male and 1% of female deaths in England and Wales each year, equivalent to a rate of 8 per 100 000. The rate increases with age, peaking for women in their 60s and for men in their 70s. Suicide is the second most common cause of mortality in 15- to 34-year-olds. Approximately 15% of people who have suffered a severe depressive disorder (requiring admission) will eventually commit suicide, with 6% doing so in the 10 years after their first admission. Suicide rates in schizophrenia sufferers are likewise high, being 20–50 times the rate in the general population; 20–40% of people with schizophrenia make suicide attempts, and 9–13% are successful.

The highest rates of suicide have been reported in rural southern India (148/100 000 in young women and 58/100 000 in young men) and in eastern Europe (30–40/100 000), while the lowest are those of Spain (3.9/100 000) and Greece (2.8/100 000), but such variations may reflect differences in reporting, which may be related to religion, as much as genuine differences. The provision of mental health care to suicidal individuals varies greatly around the world, with a recent WHO study suggesting that most receive no treatment at all. Factors that increase the risk of suicide are indicated in Table 23.16.

A distinction must be drawn between those who attempt suicide – self-harm (SH) – and those who succeed (suicides):

Table 23.16 Factors that increase the risk of suicide

Male sex
Older age
Living alone
Immigrant status
Recent bereavement, separation or divorce
Recent loss of a job or retirement
Living in a socially disorganized area
Family history of affective disorder, suicide or alcohol misuse
Previous history of affective disorder, alcohol or drug misuse
Previous suicide attempt
Addiction to alcohol or drugs
Severe depression or early dementia
Incapacitating painful physical illness

- The majority of cases of SH occur in people under 35 years of age.
- The majority of suicides occur in people aged over 60.
- Suicides are more common in men, while SH is more common in women.
- Suicides are more common in older men, although rates are falling. Rates in young men are rising fast throughout the UK and Europe.
- Suicides in women are slowly falling in the UK.
- Approximately 90% of cases of SH involve self-poisoning.
- A formal psychiatric diagnosis usually can be made retrospectively in suicide, but is unusual in SH.

There is, however, an overlap between SH and suicide. Between 1% and 2% of people who attempt suicide will kill themselves in the year following SH. The risk of suicide stays elevated in those with SH, with 0.5% per annum committing suicide in the following 20 years. In the UK, there are 100 000 cases of SH each year, and the overwhelming majority of these are seen and treated within accident and emergency departments.

The guidelines (Box 23.11) for the assessment of such patients will help ensure that the risk factors relating to suicide are covered. Indications for referral to a psychiatrist before discharge from hospital are also given.

In general, it is worth trying to interview a family member or close friend and check these points with them. Requests for immediate re-prescription on discharge should be denied, except in cases of essential medication. In such cases, however, only 3 days' supply of medication should be given, and the patient should be requested to report to their general practitioner or to their psychiatric outpatient clinic for further supplies. Occasionally, involuntary admission to hospital may be required (p. 1191).

ANXIETY DISORDERS

These are conditions in which anxiety dominates the clinical symptoms. They are classified according to whether the anxiety is persistent (general anxiety) or episodic, with the episodic conditions classified according to whether the episodes are regularly triggered by a cue (phobia) or not (panic disorder). The differential diagnoses of anxiety disorders are given in Table 23.17. A patient with one anxiety disorder may well in time develop others.

General anxiety disorder

This occurs in 4–6% of the population and is more common in women. Symptoms are persistent and often chronic.

Table 23.17 Anxiety disorders: the differential diagnosis

Psychiatric disorder	Endocrine disorder
Depressive illness	Hyperthyroidism
Obsessive-compulsive disorder	Hypoglycaemia
Presenile dementia	Phaeochromocytoma
Alcohol dependence	
Drug dependence	
Benzodiazepine withdrawal	

Box 23.11 Guidelines for the assessment of patients who harm themselves

Questions to ask: of concern if positive answer

- Was there a clear precipitant/cause for the attempt?
- Was the act premeditated or impulsive?
- Did the patient leave a suicide note?
- Had the patient taken pains not to be discovered?
- Did the patient make the attempt in strange surroundings (i.e. away from home)?
- Would the patient do it again?

Other relevant factors

- Has the precipitant or crisis resolved?
- Is there continuing suicidal intent?
- Does the patient have any psychiatric symptoms?
- What is the patient's social support system?
- Has the patient inflicted self-harm before?
- Has anyone in the family ever taken their life?
- Does the patient have a physical illness?

Indications for referral to a psychiatrist

Absolute indications include:

- Clinical depression
- Psychotic illness of any kind
- Clearly preplanned suicidal attempt which was not intended to be discovered
- Persistent suicidal intent (the more detailed the plans, the more serious the risk)
- A violent method used

Other common indications include:

- Alcohol and drug misuse
- Patients over 45 years, especially if male, and young adolescents
- Those with a family history of suicide in first-degree relatives
- Those with serious (especially incurable) physical disease
- Those living alone or otherwise unsupported
- Those in whom there is a major unresolved crisis
- Persistent suicide attempts
- Any patients who give you cause for concern

General anxiety disorder (GAD) and its related panic disorder are differential diagnoses for functional somatic syndromes, owing to the many physical symptoms that are caused by these conditions.

Clinical features

The physical and psychological symptoms are outlined in Table 23.18. The patient looks worried, has a tense posture, restless behaviour and a pale and sweaty skin. The patient takes time to go to sleep, and when asleep wakes intermittently with worry dreams. Associated conditions include the hyperventilation syndrome, which is even more common in panic disorder (Box 23.12). The patient will sigh deeply, particularly when talking about the stresses in their life.

Mixed anxiety and depressive disorder

This disorder is probably the commonest mood disorder in primary care, in which there are equal elements of both

Table 23.18 Physical and psychological symptoms of anxiety

Physical symptoms	
Gastrointestinal	Genitourinary
Dry mouth Difficulty in swallowing Epigastric discomfort Aerophagy (swallowing air) 'Diarrhoea' (usually frequency)	Increased frequency Failure of erection Lack of libido
Respiratory	Nervous system
Feeling of chest constriction Difficulty in inhaling Overbreathing Choking	Fatigue Blurred vision Dizziness Sensitivity to noise and/or light Headache Sleep disturbance Trembling
Cardiovascular	
Palpitations Awareness of missed beats Chest pain	
Psychological symptoms	
Apprehension and fear Irritability Difficulty in concentrating Distractibility	Restlessness Depersonalization Derealization

Box 23.12 The hyperventilation syndrome**Features**

Panic attacks – fear, terror and impending doom – accompanied by some or all of the following:

- dyspnoea (trouble getting a good breath in)
- palpitations
- chest pain or discomfort
- suffocating sensation
- dizziness
- paraesthesiae in hands and feet
- peri-oral paraesthesiae
- sweating
- carpopedal spasms

Cause

Overbreathing leading to a decrease in PaCO₂ and an increase in arterial pH, leading to relative hypocalcaemia.

Diagnosis

A provocation test – voluntary overbreathing for 1 minute – provokes similar symptoms; rebreathing from a large paper bag relieves them.

Management

- Explanation and reassurance is given.
- The patient is trained in relaxation techniques and slow controlled breathing.
- The patient is asked to breathe into a closed paper bag.

anxiety and depression, showing how closely associated these two abnormal mood states are.

Panic disorder

Panic disorder is diagnosed when the patient has repeated sudden attacks of overwhelming anxiety, accompanied by severe physical symptoms, usually related to both hyperventilation (Box 23.12) and sympathetic nervous system activity (palpitations, tremor, restlessness and sweating). The lifetime prevalence is 5%. People with panic disorder often have catastrophic illness beliefs during the panic attack, such as the conviction that they are about to die from a stroke or

heart attack. The fear of a stroke is related to dizziness and headache. Fear of a heart attack accompanies chest pain (atypical chest pain). The occasional patient with long-standing attacks may deny feeling anxious and simply report the physical symptoms.

Aetiology

General anxiety and panic disorders occur four or more times as commonly in first-degree relatives of affected patients. Sympathetic nervous system overactivity, increased muscle tension and hyperventilation are the common pathophysiological mechanisms. Anxiety is the emotional response to the threat of a loss, whereas depression is the response to the loss itself. There is some evidence that being bullied, with the explicit threats involved, leads to anxiety disorders in adolescents.

Phobic (anxiety) disorders

Phobias are common conditions in which intense fear is triggered by a stimulus, or group of stimuli, that are predictable and normally cause no particular concern to others (e.g. agoraphobia, claustrophobia, social phobia). This leads to avoidance of the stimulus (Box 23.13). The patient knows that the fear is irrational, but cannot control it. The prevalence of all phobias is 8%, with many patients having more than one. Many phobias of 'medical' stimuli exist (e.g. of doctors, dentists, hospitals, vomit, blood and injections) which affect the patient's ability to receive adequate healthcare.

Aetiology

Phobias may be caused by classical conditioning, in which a response (fear and avoidance) becomes conditioned to a previously benign stimulus (a lift), often after an initiating emotional shock (being stuck in a lift). In children, phobias can arise through imagined threats (e.g. stories of ghosts told in the playground). Women have twice the prevalence of phobias than men. Phobias aggregate in families, with increasing evidence of the importance of genetic factors being published.

Agoraphobia

Translated as 'fear of the market place', this common phobia (4% prevalence) presents as a fear of being away from home, with avoidance of travelling, walking down a road and supermarkets being common cues. This can be a very disabling condition, since the patient often avoids leaving home, particularly by themselves. It is often associated with *claustrophobia*, a fear of enclosed spaces.

Social phobia

This is the fear and avoidance of social situations: crowds, strangers, parties and meetings. Public speaking would be the sufferer's worst nightmare. It is suffered by 2% of the population.

Simple phobias

The commonest is the phobia of spiders (arachnophobia), particularly in women. The prevalence of simple phobias is 7% in the general population. Other common phobias include

Box 23.13 Phobias

- A phobia is an abnormal fear and avoidance of an object or situation.
- Phobias are common (8% prevalence), disabling and treatable with behaviour therapy.

insects, moths, bats, dogs, snakes, heights, thunderstorms and the dark. Children are particularly phobic about the dark, ghosts and burglars, but the large majority grow out of these fears.

Treatment of anxiety disorders

Psychological treatments

For many people with brief episodes, discussion with a doctor concerning the nature of anxiety is usually sufficient.

- **Relaxation techniques** can be effective in mild/moderate anxiety. Relaxation can be achieved in many ways, including complementary techniques such as meditation and yoga. Conventional relaxation training involves slowing down the rate of breathing, muscle relaxation and mental imagery.
- **Anxiety management** training involves two stages. In the first stage, verbal cues and mental imagery are used to arouse anxiety to demonstrate the link with symptoms. In the second stage, the patient is trained to reduce this anxiety by relaxation, distraction and reassuring self-statements.
- **Biofeedback** is useful for showing patients that they are not relaxed, even when they fail to recognize it, having become so used to anxiety. Biofeedback involves feeding back to the patient a physiological measure that is abnormal in anxiety. These measures may include electrical resistance of the skin of the palm, heart rate, muscle electromyography or breathing pattern.
- **Behaviour therapies** are treatments that are intended to change behaviour and thus symptoms. The most common and successful behaviour therapy (with 80% success in some phobias) is graded exposure, otherwise known as systematic desensitization. First, the patient rates the phobia into a hierarchy or 'ladder' of worsening fears (e.g. in agoraphobia: walking to the front door with a coat on; walking out into the garden; walking to the end of the road). Second, the patient practises exposure to the least fearful stimulus until no fear is felt. The patient then moves 'up the ladder' of fears until they are cured.
- **Cognitive behaviour therapy** (CBT) (see p. 1174) is the treatment of choice for panic disorder and general anxiety disorder because the therapist and patient need to identify the mental cues (thoughts and memories) that may subtly provoke exacerbations of anxiety or panic attacks. CBT also allows identification and alteration of the patient's 'schema', or way of looking at themselves and their situation, that feeds anxiety.

Drug treatments

Initial 'drug' treatment should involve advice to gradually cease taking anxiogenic recreational drugs such as caffeine and alcohol (which can cause a rebound anxiety and withdrawal). Prescribed drugs used in the treatment of anxiety can be divided into two groups: those that act primarily on the central nervous system, and those that block peripheral autonomic receptors.

- **Benzodiazepines** are centrally acting anxiolytic drugs. They are agonists of the inhibitory transmitter γ -aminobutyric acid (GABA). Diazepam (5 mg twice daily, up to 10 mg three times daily in severe cases), alprazolam (250–500 μ g three times daily) and chlordiazepoxide have relatively long half-lives (20–40 h) and are used as anti-anxiety drugs in the short term. Side-effects include sedation and memory problems,

Table 23.19 Withdrawal syndrome with benzodiazepines

Insomnia	Perceptual distortions
Anxiety	Hallucinations (which may be visual)
Tremulousness	Hypersensitivities (light, sound, touch)
Muscle twitchings	Convulsions

and patients should be advised not to drive while on treatment. They can cause dependence and tolerance within 4–6 weeks, particularly in those with dependent personalities. A withdrawal syndrome (Table 23.19) can occur after just 3 weeks of continuous use and is particularly severe when high doses have been given for a longer time. Thus, if a benzodiazepine drug is prescribed for anxiety, it should be given in as low a dose as possible, preferably on an 'as necessary' basis, and for not more than 2–4 weeks. A withdrawal programme from chronic use includes changing the drug to the long-acting diazepam, followed by a very gradual reduction in dosage.

- **Most SSRIs** (e.g. fluoxetine, paroxetine, sertraline, escitalopram, citalopram) are useful symptomatic treatments for general anxiety and panic disorders, as well as some phobias (social phobia), although doses higher than those used in depression are often required. Duloxetine, mirtazapine, venlafaxine and pregabalin are alternative treatments for GAD with the added benefit of possibly preventing the subsequent development of depression. Treatment response is often delayed several weeks; a trial of treatment should last 3 months.
- **Antipsychotics** such as aripiprazole or olanzapine can be effective for more severe or refractory cases.
- **Beta-blockers** are effective in reducing peripheral symptoms: many of the symptoms of anxiety are due to an increased or sustained release of adrenaline (epinephrine) and noradrenaline (norepinephrine) from the adrenal medulla and sympathetic nerves. Beta-blockers such as propranolol (20–40 mg two or three times daily) are effective in reducing peripheral symptoms such as palpitations, tremor and tachycardia, but they do not help central symptoms such as anxiety.

Acute stress reactions and adjustment disorders

Acute stress reaction

This occurs in individuals in response to exceptional physical and/or psychological stress. While severe, such a reaction usually subsides within days. The stress may be an overwhelming traumatic experience (e.g. accident, battle, physical assault, rape) or a sudden change in the social circumstances of the individual, such as a bereavement. Individual vulnerability and coping capacity play a role in the occurrence and severity of an acute stress reaction, as evidenced by the fact that not all people exposed to exceptional stress develop symptoms. Symptoms usually include an initial state of feeling 'dazed' or numb, with inability to comprehend the situation. This may be followed either by further withdrawal from the situation or by anxiety and overactivity. No treatments beyond reassurance and support are normally necessary.

Adjustment disorder

This disorder can follow an acute stress reaction and is common in the general hospital. This is a more prolonged

(up to 6 months) emotional reaction to a significant life event, with low mood joining the initial shock and consequent anxiety, but not of sufficient severity or persistence to fulfil a diagnosis of a depressive or anxiety disorder. Supportive counselling is usually a successful treatment, allowing facilitation of unexpressed feelings, elucidation of unspoken fears, and education about the likely future.

Normal grief

Normal grief immediately follows bereavement, is expressed openly, and allows a person to go through the social ceremonies and personal processes of bereavement. The three stages are, first, shock and disbelief, second, the emotional phase (anger, guilt and sadness) and, third, acceptance and resolution. This normal process of adjustment may take up to a year, with movement between all three stages occurring in a sometimes haphazard fashion.

Pathological (abnormal) grief

This is a particular kind of adjustment disorder. It can be characterized as excessive and/or prolonged grief, or even absent grieving with abnormal denial of the bereavement. Usually a relative will be stuck in grief, with insomnia and repeated dreams of the dead person, anger at doctors or even the patient for dying, consequent guilt in equal measure, and an inability to 'say good-bye' to the loved person by dealing with their effects. *Guided mourning* uses cognitive and behavioural techniques to allow the relative to stop grieving and move on in life.

Post-traumatic stress disorder (PTSD)

This is a protracted response to a stressful event or situation of an exceptionally threatening nature, likely to cause pervasive distress in almost anyone. Causes include natural or human disasters, war, serious accidents, witnessing the violent death of others, being the victim of sexual abuse, rape, torture, terrorism or hostage-taking. Predisposing factors such as personality, previously unresolved traumas, or a history of psychiatric illness may prolong the course of the syndrome. These factors are neither necessary nor sufficient to explain its occurrence, which is most related to the intensity of the trauma, the proximity of the patient to the traumatic event, and how prolonged or repeated it was. Functional brain scan research suggests a possible neurophysiological relationship with obsessive-compulsive disorder (p. 1181).

Clinical features

The typical symptoms of PTSD include:

- **'Flashbacks'**: repeated vivid reliving of the trauma in the form of intrusive memories, often triggered by a reminder of the trauma
- **Insomnia**, usually accompanied by nightmares, the nocturnal equivalent of flashbacks
- **Emotional blunting**, emptiness or 'numbness', alternating with
 - **intense anxiety** with exposure to events that resemble an aspect of the traumatic event, including anniversaries of the trauma
- **Avoidance** of activities and situations reminiscent of the trauma
- **Emotional detachment** from other people
- **Hypervigilance** with autonomic hyperarousal and an enhanced startle reaction.

This clinical picture represents the severe end of a spectrum of emotional reactions to trauma, which might

alternatively take the form of an adjustment or mood disorder. The course is often fluctuating but recovery can be expected in two-thirds of cases at the end of the first year. Complications include depressive illness and alcohol misuse. In a small proportion of cases the condition may show a chronic course over many years and a transition to an enduring personality change.

Treatment and prevention

Compulsory *psychological debriefing* immediately after a trauma does not prevent PTSD and may be harmful. Prevention is better achieved by the support offered by others who were also involved. Trauma focused CBT is often effective. *Eye movement desensitization and reprocessing* (EMDR) is equally effective treatment and may require fewer sessions. SSRIs and venlafaxine have a place in the management of chronic PTSD, but drop-out from pharmacotherapy is common.

The adult consequences of childhood sexual and physical abuse

Estimates of the prevalence of childhood sexual abuse vary depending on definition but there is reasonable evidence that 20% of women and 10% of men suffered significant, coercive and inappropriate sexual activity in childhood. The abuser is usually a member of the family or known to the child. The likelihood of long-term consequences is determined by:

- an earlier age of onset
- the severity of the abuse
- the repeated nature and duration of the period of abuse
- the association with physical abuse.

Consequent adult psychiatric disorders include depressive illness, substance misuse, eating disorders, borderline personality disorder and deliberate self-harm. Other negative outcomes include a decline in socioeconomic status, sexual problems, prostitution and difficulties in forming adult relationships.

Repeated childhood physical and emotional abuse or neglect may also affect emotional and personality development, predisposing the adult to similar psychiatric disorders. Those with repeated abuse are more likely to have long-term physical stress related consequences, such as hypothalamic-pituitary-adrenal axis downregulation and smaller brain hippocampal sizes.

Psychodynamic psychotherapy

Psychodynamic psychotherapy is derived from psychoanalysis and is based on a number of key analytical concepts. These include Freud's ideas about psychosexual development, defence mechanisms, free association as the method of recall, and the therapeutic techniques of interpretation, including that of transference, defences and dreams. Such therapy usually involves once-weekly sessions, the length of treatment varying between 3 months and 2 years. The long-term aim of such therapy is twofold: symptom relief and personality change. Psychodynamic psychotherapy is classically indicated in the treatment of unresolved conflicts in early life, as might be found in non-psychotic and personality disorders, but there is no convincing evidence concerning its superiority over alternative forms of treatment.

Cognitive analytical therapy

Cognitive analytical therapy is an integration of cognitive behaviour therapy and psychodynamic therapy. It is a

FURTHER READING

Stein D, Seedat S, Iversen A et al. Post-traumatic stress disorder. *Lancet* 2006; 369:139–144.

short-term therapy that involves the patient and therapist recognizing the origins of a recurrent problem, reformulating how it continues to occur, and revising other ways of coping and internalizing it, using both the transference of the patient-therapist relationship and behavioural experiments.

Obsessive-compulsive disorder

Obsessive-compulsive disorder (OCD) is characterized by obsessional ruminations and compulsive rituals. It is particularly associated with and/or secondary to both depressive illness and *Gilles de la Tourette's syndrome* (p. 1122). The prevalence is between 1% and 2% in the general population, and patients often do not seek help. There is an equal distribution by gender, and the mean age of onset ranges from 20 to 40 years.

Clinical features

The obsessions and compulsions are time consuming and intrusive so that they affect functioning and cause considerable distress. Ruminations are often unpleasant repetitive thoughts, out of character, such as being dirty or violent. This can lead to a constant need to check that everything and everyone is alright and that things have been done correctly, and reassurance cannot remove the doubt that persists. Some rituals are derived from superstitions, such as actions repeated a fixed number of times, with the need to start again if interrupted. When severe and primary, OCD can last for many years and may be resistant to treatment. However, obsessional symptoms commonly occur in other disorders, most notably depressive illness and schizophrenia, and remit with the resolution of the primary disorder.

Minor degrees of obsessional symptoms and compulsive rituals or superstitions are common in people who are not ill or in need of treatment, particularly in times of stress. The mildest grade is that of obsessional personality traits such as over-conscientiousness, tidiness, punctuality and other attitudes and behaviours indicating a strong tendency towards conformity and inflexibility. Such individuals are *perfectionists* who are intolerant of shortcomings in themselves and others, and take pride in their high standards. When such traits are so marked that they dominate other aspects of the personality, in the absence of clear-cut OCD, the diagnosis is obsessional (anankastic) personality (see p. 1190).

Aetiology

Genetic

OCD is found in 5–7% of the first-degree relatives. Twin studies showed 80–90% concordance in monozygotic twins and about 50% in dizygotic twins. Genetic factors account for more of the variance in childhood onset cases than in those who develop it as an adult.

Biological model

Neuroimaging studies suggest dysfunction in the orbito-striatal area (including the caudate nucleus) and dorsolateral prefrontal cortex combined with abnormalities in serotonergic (underactive) and glutamatergic (overactive) neurotransmission. Further support for this model comes from an association with a number of neurological disorders involving dysfunction of the striatum, including Parkinson's disease, Huntington's and Sydenham's chorea. The latter has also been associated with OCD and tic disorders in the paediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS). This is a rare condition in

children following group A haemolytic streptococcal infection. OCD also can follow head trauma.

Cognitive-behavioural model

Most people have the occasional intrusive thoughts, but would ordinarily dismiss these as meaningless and not focus upon them further. These develop into an obsession when they assume great significance to the individual, causing greater anxiety. This anxiety motivates suppression of these thoughts and ritual behaviours are developed to further reduce anxiety.

Treatment

Psychological treatments

Cognitive behavioural therapy focusing on exposure and response prevention is reasonably effective. This involves confronting the anxiety provoking stimulus in a controlled environment and not performing the associated ritual. The aim is for the individual to habituate to the stimulus, thus reducing anxiety. Since it provokes anxiety, the drop-out rate is often high.

Physical treatment

Tricyclic antidepressants and serotonin reuptake inhibitors. Clomipramine (a tricyclic) and the SSRIs are the mainstay of drug treatment. Their efficacy is independent of their antidepressant action but the doses required are usually some 50–100% higher than those effective in depression. Although many sufferers respond, relapse rates on discontinuation are high. Three months' treatment with maximum tolerated doses may be necessary for a positive response and in those who fail to respond, the addition of an antipsychotic significantly improves outcome, especially when tics occur co-morbidly. Positive correlations between reduced severity of OCD and decreased orbitofrontal and caudate metabolism following behavioural and SSRI treatments have been demonstrated in a number of studies.

Anti-glutamatergic agents. Recent studies have suggested that riluzole may be effective. A randomized, double-blind, placebo-controlled augmentation trial of D-cycloserine (an N-methyl-D-aspartic acid (NMDA) receptor agonist) administered in combination with CBT, prior to sessions, has suggested that this may speed treatment response time.

Deep brain stimulation. This is a non-ablative, and therefore potentially reversible, surgical technique that involves the electrical stimulation of the basal ganglia by implanted electrodes, creating a 'functional lesion'. Although this has had success, often impressively so in intractable cases, issues still remain regarding subject selection and the optimum anatomical targets.

Psychosurgery. This is very occasionally recommended in cases of chronic and severe OCD that has not responded to other treatments. The development of stereotactic techniques has led to the replacement of the earlier, crude leucotomies with more precise surgical interventions such as subcaudate tractotomy and cingulotomy, with small yttrium radioactive implants, which induce lesions in the cingulate area or the ventromedial quadrant of the frontal lobe.

Prognosis

Two-thirds of cases improve within a year. The remainder run a fluctuating or persistent course. The prognosis is worse when the personality is obsessional or anankastic and the OCD is primary and severe.

ALCOHOL MISUSE AND DEPENDENCE

A wide range of physical, social and psychiatric problems are associated with excessive drinking. Alcohol misuse occurs when a patient is drinking in a way that regularly causes problems to the patient or others.

- **The problem drinker** is one who causes or experiences physical, psychological and/or social harm as a consequence of drinking alcohol. Many problem drinkers, while heavy drinkers, are not physically addicted to alcohol.
- **Heavy drinkers** are those who drink significantly more in terms of quantity and/or frequency than is safe to do in the long term.
- **Binge drinkers** are those who drink excessively in short bouts, usually 24–48 h long, separated by often quite lengthy periods of abstinence. Their overall monthly or weekly alcohol intake may be relatively modest.
- **Alcohol dependence** is defined by a physical dependence on or addiction to alcohol. The term 'alcoholism' is a confusing one with off-putting connotations of vagrancy, 'meths' drinking and social disintegration. It has been replaced by the term 'alcohol dependence syndrome'.

Epidemiology of alcohol misuse

A total of 20% of men and 10% of women drink more than double the recommended limits of 3 units a day of alcohol for men, and 2 units for women in the UK. The amount of alcohol consumed in the UK has doubled over the last 50 years. Some 4% of men and 2% of women report alcohol withdrawal symptoms, suggesting dependence. Approximately one in five male admissions to acute medical wards is directly or indirectly due to alcohol. People with serious drinking problems have a two to three times increased risk of dying compared with members of the general population of the same age and sex.

Table 23.20 provides an approximate estimate of what can be expected in an average individual in the way of behavioural impairment resulting from a particular blood alcohol level. The amount of alcohol is measured for convenience in units which contain about 8 g of absolute alcohol and raises the blood alcohol concentration by about 15–20 mg/dL, the amount that is metabolized in 1 h. One unit of alcohol is found in half a pint of ordinary beer (3.5% alcohol by volume, ABV) and 125 mL of 9% wine. However, some beer and most lager is now 5% ABV; 3 units per pint. Wine is often 13% ABV and sold in 175 mL glasses; 2–3 units per glass.

Table 23.20 Behavioural effects of alcohol

Blood alcohol concentration (BAC) (mg/dL)	Expected effect
20–99	Impaired coordination, euphoria
100–199	Ataxia, poor judgement, labile mood
200–299	Marked ataxia and slurred speech; poor judgement, labile mood, nausea and vomiting
300–399	Stage 1 anaesthesia, memory lapse, labile mood
400+	Respiratory failure, coma, death

Detection

Alcohol misuse should be suspected in any patient presenting with one or more physical problems commonly associated with excessive drinking (see p. 226). Alcohol misuse may also be associated with a number of psychiatric symptoms/disorders and social problems (Table 23.21).

Guidelines

The patient's frequency of drinking and quantity drunk during a typical week should be established:

- Up to 21 units of alcohol a week for men and 14 units for women: this carries no long-term health risk
- 21–35 units a week for men and 14–24 units for women: there is unlikely to be any long-term health damage, provided the drinking is spread throughout the week
- Over 36 units a week for men and 24 for women: damage to health becomes increasingly likely
- Above 50 units a week for men and 35 for women: this is a definite health hazard.

Diagnostic markers of alcohol misuse

Laboratory parameters indicating alcohol misuse in recent weeks include elevated γ -glutamyl transpeptidase (γ -GT) and mean corpuscular volume (MCV). Blood or breath alcohol tests are useful in anyone suspected of very recent drinking.

Alcohol dependence syndrome

Dependence is a pattern of repeated self-administration that causes tolerance, withdrawal and compulsive drug-taking, the essential element of which is the continued use of the substance despite significant substance-related problems. Symptoms of alcohol dependence in a typical order of occurrence are shown in Table 23.22. Diagnostic criteria for alcohol withdrawal syndrome are shown in Table 23.23.

Table 23.21 Common alcohol-related psychological and social problems

Psychological	Social
Depression	Domestic violence
Anxiety	Marital and sexual difficulties
Memory problems	Child abuse
Delirium tremens	Employment problems
Attempted suicide	Financial difficulties
Suicide	Accidents at home, on the roads, at work
Pathological jealousy	Delinquency and crime
	Homelessness

Table 23.22 Symptoms of alcohol dependence

Unable to keep to a drink limit
Difficulty in avoiding getting drunk
Spending a considerable time drinking
Missing meals
Memory lapses, blackouts
Restless without drink
Organizing day around drink
Trembling after drinking the day before
Morning retching and vomiting
Sweating excessively at night
Withdrawal fits
Morning drinking
Increased tolerance
Hallucinations, frank delirium tremens

Table 23.23 Diagnostic criteria for alcohol withdrawal syndrome**Any three of the following:**

Tremor of outstretched hands, tongue or eyelids
 Sweating
 Nausea, retching or vomiting
 Tachycardia or hypertension
 Anxiety
 Psychomotor agitation
 Headache
 Insomnia
 Malaise or weakness
 Transient visual, tactile or auditory hallucinations or illusions
 Grand mal convulsions

The course of the alcohol dependence syndrome

About 25% of all cases of alcohol misuse will lead to chronic alcohol dependence. This most commonly ends in social incapacity, death or abstinence. Alcohol dependence syndrome usually develops after 10 years of heavy drinking (3–4 years in women). In some individuals who use alcohol to alter consciousness, obliterate conscience and defy social mores, dependence and loss of control may appear in only a few months or years.

Delirium tremens (DTs)

Delirium tremens is the most serious withdrawal state and occurs 1–3 days after alcohol cessation, so is commonly seen 1–2 days after admission to hospital. Patients are disorientated, agitated, and have a marked tremor and visual hallucinations (e.g. insects or small animals coming menacingly towards them). Signs include sweating, tachycardia, tachypnoea and pyrexia. Complications include dehydration, infection, hepatic disease or the Wernicke–Korsakoff syndrome (p. 1147).

Causes of alcohol dependence

Genetic factors. Sons of alcohol-dependent people who are adopted by other families are four times more likely to develop drinking problems than are the adopted sons of non-alcohol misusers. Genetic markers include dopamine-2 receptor allele A1, alcohol dehydrogenase subtypes and monoamine oxidase B activity, but they are not specific.

Environmental factors. One in 10 boys who grow up in a household where neither parent misused alcohol subsequently become alcohol dependent, compared with one in four of those reared by alcohol-misusing fathers and one in three of those reared by alcohol-misusing mothers.

Biochemical factors. Several factors have been suggested, including abnormalities in alcohol dehydrogenase, neurotransmitter substances and brain amino acids, such as GABA. There is no conclusive evidence that these or other biochemical factors play a causal role.

Psychiatric illness. This is an uncommon cause of addictive drinking but it is a treatable one. Some depressed patients drink excessively in the hope of raising their mood. People with anxiety states or phobias are also at risk.

Excess consumption in society. The prevalence of alcohol dependence and problems correlates with the general level (*per capita* consumption) of alcohol use in a society. This, in turn, is determined by factors that may control overall consumption – including price, licensing laws, availability, and the societal norms concerning the use and misuse of alcohol.

Box 23.14 Management of delirium tremens (DTs)

General measures

- Admit the patient to a medical bed.
- Correct electrolyte abnormalities and dehydration.
- Treat any co-morbid disorder (e.g. infection).
- Give parenteral thiamine slowly (250 mg daily for 3–5 days in the absence of Wernicke–Korsakoff, W–K syndrome).
- Give parenteral thiamine slowly (500 mg daily for 3–5 days with W–K encephalopathy. *Note:* beware anaphylaxis).
- Give prophylactic phenytoin or carbamazepine, if previous history of withdrawal fits.

Specific drug treatment

Give one of the following orally:

- Diazepam 10–20 mg
 - Chlordiazepoxide 30–60 mg
- Repeat 1 h after last dose depending on response.

Fixed-schedule regimens

- Diazepam 10 mg every 6 h for 4 doses, then 5 mg 6-hourly for 8 doses OR
- Chlordiazepoxide 30 mg every 6 h for 4 doses, then 15 mg 6-hourly for 8 doses.

Provide additional benzodiazepine when symptoms and signs are not controlled.

Treatment

Psychological treatment of problem drinking

Successful identification at an early stage can be a helpful intervention in its own right. It should lead to:

- The provision of information concerning safe drinking levels
- A recommendation to cut down where indicated
- Simple support and advice concerning associated problems.

Such a brief intervention is effective in its own right. Successful alcohol misuse treatment involves *motivational enhancement (motivational therapy)*, feedback, education about adverse effects of alcohol, and agreeing drinking goals. A motivational approach is based on five stages of change: precontemplation, contemplation, determination, action and maintenance. The therapist uses motivational interviewing and reflective listening to allow the patient to persuade himself along the five stages to change.

This technique, cognitive behaviour therapy and 12-step facilitation (as used by Alcoholics Anonymous, AA) have all been shown to reduce harmful drinking. With addictive drinking, self-help group therapy, which involves the long-term support by fellow members of the group (e.g. AA), is helpful in maintaining abstinence. Family and marital therapy involving both the alcohol misuser and spouse may also be helpful. Families of drinkers find meeting others in a similar situation helpful (Al-Anon).

Drug treatments of problem drinking

Alcohol withdrawal and DTs

Addicted drinkers often experience considerable difficulty when they attempt to reduce or stop their drinking. Withdrawal symptoms are a particular problem and delirium tremens needs urgent treatment (Box 23.14). In the absence of DTs, alcohol withdrawal can be treated on an outpatient basis, using one of the fixed schedules in Box 23.14, so long as the patient attends daily for medication and monitoring, and has good social support. Outpatient schedules are

sometimes given over 5 days. Long-term treatment with benzodiazepines should not be prescribed in those patients who continue to misuse alcohol. Some alcohol misusers add dependence on diazepam or clomethiazole to their problems.

Drugs for prevention of alcohol dependence

Naltrexone, the opioid antagonist (50 mg per day), reduces the risk of relapse into heavy drinking and the frequency of drinking. *Acamprosate* (1–2 g/day) acts on several receptors including those for GABA, noradrenaline (norepinephrine) and serotonin. There is reasonable evidence that it reduces drinking frequency. Neither drug seems particularly helpful in maintaining abstinence. Both drug effects are enhanced by combining them with counseling, but their moderate efficacy precludes regular use.

Drugs such as *disulfiram* react with alcohol to cause unpleasant acetaldehyde intoxication and histamine release. A daily maintenance dose means that the patient must wait until the disulfiram is eliminated from the body before drinking safely. There is mixed evidence of efficacy.

Oral thiamine (300 mg/day) can prevent Wernicke–Korsakoff syndrome (p. 1147) in heavy drinkers.

Outcome

Research suggests that 30–50% of alcohol-dependent drinkers are abstinent or drinking very much less up to 2 years following traditional intervention. It is too early to be certain of the long-term outcome of patients treated with the latest psychological and pharmacological therapies.

DRUG MISUSE AND DEPENDENCE

In addition to alcohol and nicotine, there are a number of psychotropic substances that are taken for their effects on mood and other mental functions (Table 23.24).

Causes of drug misuse

There is no single cause of drug misuse and/or dependence. Three factors appear commonly, in a similar way to alcohol problems:

- The availability of drugs
- A vulnerable personality
- Social pressures, particularly from peers.

Table 23.24 Commonly used drugs of misuse and dependence

Stimulants	Methylphenidate Phenmetrazine Phencyclidine ('angel dust') Cocaine Amphetamine derivatives Ecstasy (MDMA)
Hallucinogens	Cannabis preparations Solvents Lysergic acid diethylamide (LSD) Mescaline
Narcotics	Morphine Heroin Codeine Pethidine Methadone
Tranquillizers	Barbiturates Benzodiazepines

Once regular drug-taking is established, pharmacological factors determine dependence.

Solvents

Of the adolescents in the UK, 1% sniff solvents for their intoxicating effects. Tolerance develops over weeks or months. Intoxication is characterized by euphoria, excitement, a floating sensation, dizziness, slurred speech and ataxia. Acute intoxication can cause amnesia and visual hallucinations. In 2004, there were 47 deaths recorded in the UK from solvent misuse; 13 of these were among under 18-year-olds.

Amfetamines and related substances

These have temporary stimulant and euphoriant effects that are followed by fatigue and depression, with the latter sometimes prolonged for weeks. Psychological rather than true physical dependence occurs with amphetamine sulphate ('speed'). Methyl amphetamine, also known as 'methamphetamine' or 'crystal meth', is another amphetamine psychostimulant. The particularly high potential for abuse is associated with the activation of neural reward mechanisms involving nucleus accumbens dopamine release.

In addition to a manic-like presentation, amphetamines can produce a paranoid psychosis indistinguishable from schizophrenia.

'Ecstasy' (also known as: E, white burger, white dove), is the street name for 3,4-methylenedioxy-methamphetamine (MDMA), a psychoactive phenylisopropylamine, synthesized as an amphetamine derivative. It is a psychedelic drug, which is often used as a 'dance drug'. It has a brief duration of action (4–6 h). Deaths have been reported from malignant hyperpyrexia and dehydration. Acute renal and liver failure can occur.

Cocaine (p. 917)

Cocaine is a central nervous system stimulant (with similar effects to amphetamines) derived from *Erythroxylon coca* trees grown in the Andes. In purified form it may be taken by mouth, snorted or injected. If cocaine hydrochloride is converted to its base ('crack'), it can be smoked. This causes an intense stimulating effect, and 'free-basing' is common. Compulsive use and dependence occur more frequently among users who are free-basing. Dependent users take large doses and alternate between withdrawal phenomena of depression, tremor and muscle pains, and the hyperarousal produced by increasing doses. Prolonged use of high doses produces irritability, restlessness, paranoid ideation and occasionally convulsions. Persistent sniffing of the drug can cause perforation of the nasal septum. Overdoses cause death through myocardial infarction, cerebrovascular disease, hyperthermia and arrhythmias (p. 917).

Hallucinogenic drugs

Hallucinogenic drugs, such as lysergic acid diethylamide (LSD) and mescaline, produce distortions and intensifications of sensory perceptions, as well as frank hallucinations in acute intoxication. Psychosis is a long-term complication.

Cannabis

Cannabis (also known as: grass, pot, skunk, spliff, marijuana) is a drug widely used in some subcultures. It is derived from the dried leaves and flowers of the plant *Cannabis sativa*. It

can cause tolerance and dependence. Hashish is the dried resin from the flower tops, whilst marijuana refers to any part of the plant. The drug, when smoked, seems to exaggerate the pre-existing mood, be it depression, euphoria or anxiety. It has specific analgesic properties. Cannabis use has increased in the UK recently, especially use of more potent 'skunk'. An amotivational syndrome with apathy and memory problems has been reported with chronic daily use. Cannabis may of itself sometimes cause psychosis in the right circumstances (see below).

Tranquillizers

Drugs causing dependence include barbiturates and benzodiazepines. Benzodiazepine dependence is common and may be iatrogenic, when the drugs are prescribed and not discontinued. Discontinuing treatment with benzodiazepines may cause withdrawal symptoms (Table 23.19). For this reason, withdrawal should be supervised and gradual.

Opiates

Physical dependence occurs with morphine, heroin and codeine as well as with synthetic and semisynthetic opiates such as methadone, pethidine and fentanyl. These substances display cross-tolerance – the withdrawal effects of one are reduced by administration of another. The psychological effects of opiates are a calm, slightly euphoric mood associated with freedom from physical discomfort and a flattening of emotional response. This is believed to be due to the attachment of morphine and its analogues to endorphin receptors in the CNS. Tolerance to this group of drugs is rapidly developed and marked, but is rapidly lost following abstinence. The *opiate withdrawal syndrome* consists of a constellation of signs and symptoms (Table 23.25) that reaches peak intensity on the 2nd or 3rd day after the last dose of the opiate. These rapidly subside over the next 7 days. Withdrawal is dangerous in people with heart disease or other chronic debilitating conditions.

Opiate addicts have a relatively high mortality rate, owing to both the ease of accidental overdose and the blood-borne infections associated with shared needles. Heart disease (including infective endocarditis), tuberculosis and AIDS are common causes of death, while the complications of hepatitis B and C are also common.

Treatment of chronic misuse

Blood and urine screening for drugs is required in circumstances where drug misuse is suspected (Table 23.24). When

a patient with an opiate addiction is admitted to hospital for another health problem, advice should be sought from a psychiatrist or drug misuse clinic regarding management of their addiction while an inpatient.

The treatment of chronic dependence is directed towards helping the patient either to live without drugs or to prevent secondary ill-health. Patients need help and advice in order to avoid a withdrawal syndrome. Some people with opiate addiction who cannot manage abstinence may be maintained on oral methadone. In the UK, only specially licensed doctors may legally prescribe heroin and cocaine to an addict for maintenance treatment of addiction. An overdose should be treated immediately with the opioid antagonist naloxone. Recently, injectable diacetylmorphine, the active ingredient in heroin, has been proposed as a more effective alternative to methadone but adverse effects (accidental overdose and seizures) remain a potential concern.

Drug-induced psychosis

Drug-induced psychosis has been reported with amphetamine and its derivatives, and cocaine and hallucinogens. It can occur acutely after drug use, but is more usually associated with chronic misuse. Psychoses are characterized by vivid hallucinations (usually auditory, but often in more than one sensory modality), misidentifications, delusions and/or ideas of reference (often of a persecutory nature), psychomotor disturbances (excitement or stupor) and an abnormal affect. ICD-10 requires that the condition occurs within 2 weeks and usually within 48 h of drug use and that it should persist for more than 48 h but not more than 6 months.

Cannabis use can result in anxiety, depression or hallucinations. Manic-like psychoses occurring after long-term cannabis use have been described, but seem more likely to be related to the toxic effects of heavy ingestion. However, a meta-analysis suggests that ever taking cannabis increases the risk of psychosis by 40%, daily cannabis use doubles the risk of psychosis, and that 14% of schizophrenia in the UK would be prevented if cannabis use ceased. The risk is higher in people taking cannabis early in their lives and with a heavy consumption.

SCHIZOPHRENIA

The group of illnesses conventionally referred to as 'schizophrenia' is diverse in nature and covers a broad range of perceptual, cognitive and behavioural disturbances. The point prevalence of the condition is 0.5% throughout the world, with equal gender distribution. A physician primarily needs to know how to recognize schizophrenia, what problems it might present with in the general hospital, and how it is treated.

Causes

No single cause has been identified. Schizophrenia is likely to be a disease of neurodevelopmental disconnection caused by an interaction of genetic and multiple environmental factors that affect brain development. It is likely that daily cannabis use is a risk factor. The genetic aetiology is likely to be polygenic and non-mendelian. Schizophrenia has a heritability of about 60%. Functional neuroimaging studies and histology point towards alterations in prefrontal and less consistently temporal lobe function, with enlarged lateral ventricles and disorganized cytoarchitecture in the hippocampus, supporting the neurodevelopmental theory of aetiology. Dopamine excess (D_2) is the oldest and most widely

accepted neurochemical hypothesis, although this may only explain one group of symptoms (the positive ones). The cognitive impairments in schizophrenia may be related to dopamine D₁ abnormalities. The interaction between serotonergic and dopaminergic systems is likely to play a role, although direct evidence is currently lacking. Additional hypotheses involving glutamate (NMDA) and GABA systems are currently also under scrutiny.

Clinical features

The illness can begin at any age but is rare before puberty. The peak age of onset is the early 20s. The symptoms that are diagnostic of the condition have been termed *first rank symptoms* and were described by the German psychiatrist Kurt Schneider. They consist of:

- Auditory hallucinations in the third person, and/or voices commenting on their behaviour
- Thought withdrawal, insertion and broadcast
- Primary delusion (arising out of nothing)
- Delusional perception
- Somatic passivity and feelings – patients believe that thoughts, feelings or acts are controlled by others.

The more of these symptoms a patient has, the more likely the diagnosis is schizophrenia, but these symptoms may also occur in other psychoses. Other symptoms of *acute* schizophrenia include behavioural disturbances, other hallucinations, secondary (usually persecutory) delusions and blunting of mood. Schizophrenia is sometimes divided into 'positive' (type 1) and 'negative' (type 2) types:

Positive schizophrenia is characterized by acute onset, prominent delusions and hallucinations, normal brain structure, a biochemical disorder involving dopaminergic transmission, a good response to neuroleptics, and a better outcome.

Negative schizophrenia is characterized by a slow, insidious onset, a relative absence of acute symptoms, the presence of apathy, social withdrawal, lack of motivation, underlying brain structure abnormalities and poor neuroleptic response.

Chronic schizophrenia

This is characterized by long duration and 'negative' symptoms of underactivity, lack of drive, social withdrawal and emotional emptiness.

Differential diagnosis

Schizophrenia should be distinguished from:

- Organic mental disorders (e.g. partial complex epilepsy)
- Mood (affective) disorders (e.g. mania)
- Drug psychoses (e.g. amphetamine psychosis)
- Personality disorders (schizotypal).

In older patients, any acute or chronic brain syndrome can present in a schizophrenia-like manner. A helpful diagnostic point is that altered consciousness and disturbances of memory do not occur in schizophrenia, and visual hallucinations are unusual.

A *schizoaffective psychosis* describes a clinical presentation in which clear-cut affective and schizophrenic symptoms co-exist in the same episode.

Prognosis

The prognosis of schizophrenia is variable: 15–25% of people with schizophrenia recover completely, about 70% will have

relapses and may develop mild to moderate negative symptoms, and about 10% will remain seriously disabled.

Treatment

The best results are obtained by combining drug and social treatments.

Antipsychotic (neuroleptic) drugs

These act by blocking the D₁ and D₂ groups of dopamine receptors. Such drugs are most effective against acute, positive symptoms and are least effective in the management of chronic, negative symptoms. Complete control of positive symptoms can take up to 3 months, and premature discontinuation of treatment can result in relapse.

As antipsychotic drugs block both D₁ and D₂ dopamine receptors, they usually produce extrapyramidal side-effects. This limits their use in maintenance therapy of many patients. They also block adrenergic and muscarinic receptors and thereby cause a number of unwanted effects (Table 23.26).

The neuroleptic malignant syndrome is an infrequent but potentially dangerous unwanted effect. This is a medical emergency and should be managed on a medical ward. It occurs in 0.2% of patients on *neuroleptic drugs*, particularly the potent dopaminergic antagonists, e.g. haloperidol. Symptoms occur a few days to a few weeks after starting treatment and consist of hyperthermia, muscle rigidity, autonomic instability (tachycardia, labile blood pressure, pallor) and a fluctuating level of consciousness. Investigations show a raised creatine kinase, raised white cell count and abnormal liver biochemistry. The more severe consequences include renal failure, pulmonary embolus and death. Treatment consists of stopping the drug and general resuscitation, e.g. temperature reduction. Bromocriptine enhances dopaminergic activity and dantrolene will reduce muscle tone but no treatment has proven benefit.

Pregnancy. Data on the potential teratogenicity of antipsychotic (neuroleptic) medications are still limited. The disadvantages of not treating during pregnancy have to be balanced against possible developmental risks to the fetus. The butyrophenones (e.g. haloperidol) are probably safer than the phenothiazines. Subsequent management decisions on dosage will depend primarily on the ability to avoid side-effects, since the antiparkinsonian agents are still believed to be teratogenic and should be avoided.

Table 23.26 Unwanted effects of antipsychotic drugs

Weight gain	

Typical or first generation antipsychotics

Phenothiazines were the first group of antipsychotics to be developed but are used less frequently now. Chlorpromazine (100–1000 mg daily) is the drug of choice when a more sedating drug is required. Trifluoperazine is used when sedation is undesirable. Fluphenazine decanoate is used as a long-term prophylactic to prevent relapse, as a depot injection (25–100 mg i.m. every 1–4 weeks).

Butyrophenones (e.g. haloperidol 2–30 mg daily) are also powerful antipsychotics, used in the treatment of acute schizophrenia and mania. They are likely to cause a dystonia and/or extrapyramidal side-effects, but are much less sedating than the phenothiazines.

Atypical antipsychotics or serotonin dopamine antagonists (SDAs)

These drugs, also referred to as the 'second generation antipsychotics', are 'atypical' in that they block D_2 receptors less than D_1 and thus cause fewer extrapyramidal side-effects and less tardive dyskinesia. They are now recommended as first-line drugs for newly diagnosed schizophrenia and for patients taking typical antipsychotics but with significant adverse effects.

Risperidone is a benzisoxazole derivative with combined dopamine D_2 receptor and $5HT_{2A}$ -receptor blocking properties. Dosage ranges from 6 to 10 mg/day. The drug is not markedly sedative and the overall incidence and severity of extrapyramidal side-effects is lower than with more conventional antipsychotics. Hyperprolactinaemia can be problematic and prolactin levels should be monitored. Paliperidone is an active metabolite of risperidone, available in oral and depot (4 weekly) preparations.

Olanzapine has affinity for $5HT_2$, D_1 , D_2 , D_4 , and muscarinic receptor sites. Clinical studies indicate it to have a lower incidence of extrapyramidal side-effects. The apparent better compliance with the drug may be related to its lower side-effect profile and its once-daily dosage of 5–15 mg. Weight gain is a problem with long-term treatment and there is an increased risk of type 1 diabetes mellitus with this and other atypicals.

Neither risperidone nor olanzapine seems as specific a treatment for intractable chronic schizophrenia as clozapine. *Other atypical antipsychotics* include amisulpride, lurasidone, sulpiride, zotepine, ziprasidone and quetiapine, the latter causing less hyperprolactinaemia. Those taking atypical antipsychotics should have regular monitoring of their body mass index, cholesterol levels, blood sugar and QT interval on ECG. No more than one antipsychotic should be prescribed routinely.

Clozapine is used in patients who have intractable schizophrenia who have failed to respond to at least two conventional antipsychotic drugs or as first-line therapy. This drug is a dibenzodiazepine with a relative high affinity for D_4 dopamine receptors, as compared with D_1 , D_2 , D_3 and D_5 , in addition to muscarinic and α -adrenergic receptors. It additionally acts as a partial agonist at $5HT_{1A}$ receptors, which may be of benefit in treating 'negative' symptoms of psychosis. Functional brain scans have shown that clozapine selectively blocks limbic dopamine receptors more than striatal ones, which is probably why it causes considerably fewer extrapyramidal side-effects. Clozapine exercises a dramatic therapeutic effect on both intractable positive and negative symptoms. However, it is expensive and produces severe agranulocytosis in 1–2% of patients. Therefore, in the UK for example, it can only be prescribed to registered patients by doctors and pharmacists registered with a patient-monitoring service. The starting dose is 25 mg per day with

a maintenance dose of 150–300 mg daily. White cell counts should be monitored weekly for 18 weeks and then 2-weekly for the length of treatment. In addition to its antipsychotic actions, clozapine may also help reduce aggressive and hostile behaviour and the risk of suicide. It can cause considerable weight gain and sialorrhoea. There is an increased risk of diabetes mellitus and gastrointestinal hypomotility resulting in a functional obstruction has also been reported.

Psychological treatment

This consists of reassurance, support and a good doctor-patient relationship. Psychotherapy of an intensive or exploratory kind is contraindicated. In contrast, individual cognitive behaviour therapy can help reduce the intensity of delusions.

Social treatment

Social treatment involves attention being paid to the patient's environment and social functioning. Family education can help relatives and partners to provide the optimal amount of emotional and social stimulation, so that not too much emotion is expressed (a risk for relapse). Sheltered employment is usually necessary for the majority of sufferers if they are to work. Assertive outreach mental health teams will follow up those poorly adhering to treatment.

Medical presentations related to treatment

The motor side-effects of neuroleptics are the commonest reason for a patient with schizophrenia to present to a physician, followed by self-harm. Acute dystonia normally arises in patients newly started on neuroleptics, causing torticollis. Extrapyramidal side-effects are common and present in the same way as Parkinson's disease. They remit on stopping the drug and with antimuscarinic drugs, e.g. procyclidine. Akathisia is a motor restlessness, most commonly affecting the legs. It is similar to the restless legs syndrome, but apparent during the day. Amenorrhoea and galactorrhoea can be caused by dopamine antagonists. Postural hypotension can affect the elderly, and neuroleptics can be the cause of delirium in the elderly, if their antimuscarinic effects are prominent.

Long-term benefits outweigh the risks in most cases and long-term treatment is associated with a lower mortality rate when compared with no treatment. In this respect, the atypical antipsychotics are preferable to the typical antipsychotics and clozapine is the class leader in this regard.

ORGANIC MENTAL DISORDERS

Organic brain disorders result from structural pathology, as in dementia, or from disturbed central nervous system (CNS) function, as in fever-induced delirium. They do not include mental and behavioural disorders due to alcohol and misuse of drugs, which are classified separately.

Delirium

Delirium, also termed *toxic confusional state* and *acute organic psychosis*, is an acute or subacute brain failure in which impairment of attention is accompanied by abnormalities of perception and mood. It is the most common psychosis seen in the general hospital setting, where it occurs in 14–24% of patients. This rises in specialist populations such as intensive care (70–87%). Confusion is usually worse at night, with consequent sleep reversal, so that the patient is asleep in the day and awake all night. During the acute phase, thought and speech are incoherent, memory is

Drug/alcohol withdrawal
Postoperative states

impaired and misperceptions occur. Episodic visual hallucinations (or illusions) and persecutory delusions occur. As a consequence, the patient may be frightened, suspicious, restless and uncooperative.

A developing, deteriorating or damaged brain predisposes a patient to develop delirium (Table 23.27). A large number of diseases may cause delirium, particularly in elderly patients. Some causes of delirium are listed in Table 23.28. Delirium tremens should be considered in the differential diagnosis (p. 1183) as well as Lewy body dementia (p. 1147). Diagnostic criteria are given in Box 23.15.

Management

History should be taken from a witness. Examination may reveal the cause. Investigation and treatment of the underlying physical disease should be undertaken (Table 23.28). The patient should be carefully nursed and rehydrated in a quiet single room with a window that does not allow exits. If a high fever is present, the patient's temperature should be reduced.

**Box 23.15** Delirium: diagnostic criteria (derived from DSM-IV-TR)

- Disturbance of consciousness:
 - ↓ clarity of awareness of environment
 - ↓ ability to focus, sustain or shift attention
- Change in cognition:
 - memory deficit, disorientation, language disturbance, perceptual disturbance
- Disturbance develops over a short period (hours or days)
- Fluctuation over the course of a day

All current drug therapy should be reviewed and, where possible, stopped. Psychoactive drugs should be avoided if possible (because of their own risk of exacerbating delirium). In severe delirium, haloperidol is an effective choice, the daily dose usually ranging between 1.5 mg (in the elderly) and 30 mg per day. Benzodiazepines should not be used as first-line medication and may prolong confusion. If necessary, the first dose can be administered intramuscularly. Olanzapine is an effective alternative, especially if given at night for insomnia.

Prognosis of delirium

Delirium usually clears within a week or two, but brain recovery usually lags behind the recovery from the causative physical illness. The prognosis depends not only on the successful treatment of the causative disease, but also on the underlying state of the brain. Some 25% of the elderly with delirium will have an underlying dementia; 15% of patients do not survive their underlying illness; 40% are in institutional care at 6 months.

EATING DISORDERS

Obesity

This is the commonest eating disorder (see p. 195) and has become epidemic in some developed countries. It is usually caused by a combination of constitutional and social factors, but a binge eating disorder and psychological determinants of 'comfort eating' should be excluded.

Anorexia nervosa

The main clinical criteria for diagnosis are:

- A body weight more than 15% below the standard weight, or a body mass index (BMI) below 17.5 (ICD-10)
- Weight loss is self-induced by avoidance of fattening foods, vomiting, purging, exercise, or appetite suppressants
- A distortion of body image so that the patient regards her/himself as fat when she/he is thin
- A morbid fear of fatness
- Amenorrhoea in women.

Clinical features include:

- Onset usually in adolescence
- A previous history of faddish eating
- The patient generally eats little, yet is obsessed by food
- Excessive exercising.

The physical consequences of anorexia include sensitivity to cold, constipation, hypotension and bradycardia. In most cases, amenorrhoea is secondary to the weight loss. In those who also binge and vomit or abuse purgatives, there may be hypokalaemia and alkalosis.

Witlox J, Eurelings LS, de Jonghe JF et al. Delirium in elderly patients and the risk of postdischarge mortality, institutionalization, and dementia: a meta-analysis. *JAMA* 2010; 304:443–451.

Prevalence

Case register data suggest an incidence rate of 19/100 000 females aged between 15 and 34 years. Surveys have suggested a prevalence rate of approximately 1% among schoolgirls and university students. However, many more young women have amenorrhoea accompanied by less weight loss than the 15% required for the diagnosis. The condition is much less common among men (ratio of 1:10).

Aetiology

Biological factors

Genetic. Some 6–10% of siblings of affected women suffer from anorexia nervosa. There is an increased concordance amongst monozygotic twins, suggesting a genetic predisposition.

Hormonal. The reductions in sex hormones and down-regulation of the hypothalamic-pituitary-adrenal axis are secondary to malnutrition and usually reversed by refeeding.

Psychological factors

Individual. Anorexia nervosa has often been seen as an escape from the emotional problems of adolescence and a regression into childhood. Patients will often have had dietary problems in early life. Perfectionism and low self-esteem are common antecedents. Studies suggest that survivors of childhood sexual or other abuse are at greater risk of developing an eating disorder, usually anorexia nervosa, in adolescence.

Family. Family problems are most commonly secondary to the stress of coping with a family member with the illness.

Social and cultural factors

There is a higher prevalence in higher social classes, westernized families and in certain occupational groups (e.g. ballet dancers and nurses) and in societies where cultural value is placed on thinness.

Prognosis

The condition runs a fluctuating course, with exacerbations and partial remissions. Long-term follow-up suggests that about two-thirds of patients maintain normal weight and that the remaining one-third are split between those who are moderately underweight and those who are seriously underweight. Indicators of a poor outcome include:

- A long initial illness
- Severe weight loss
- Older age at onset
- Bingeing and purging
- Personality difficulties
- Difficulties in relationships.

Suicide has been reported in 2–5% of people with chronic anorexia nervosa. The mortality rate per year is 0.5% from all causes. The illness can quickly cause osteopenia, and later osteoporosis. More than one-third have recurrent affective illness, and various family, genetic and endocrine studies have found associations between eating disorders and depression.

Treatment

Treatment can be conducted on an outpatient basis unless the weight loss is severe and accompanied by marked cardiovascular signs and/or electrolyte and vitamin disturbances. Hospital admission may then be unavoidable and may need to be on a medical ward initially. Uncommonly, the patient's weight loss may be so severe as to be life-threatening. If the patient cannot be persuaded to enter

hospital, compulsory admission may have to be used. Inpatient treatment goals include:

- Establishing a therapeutic relationship with both the patient and her family
- Restoring the weight to a level between the ideal body weight and the patient's ideal weight
- The provision of a balanced diet, aimed at gaining 0.5–1 kg weight per week
- The elimination of purgative and/or laxative use and vomiting.

Outpatient treatment should include cognitive behavioural or interpersonal psychotherapies. Setting up a therapeutic alliance is vital. Family therapy is more effective than individual psychotherapy in adolescents and those still at home, and less effective in those who have left home. Motivational enhancement techniques are being used with some success.

Drug treatment has met with limited success, and those drugs that increase the QTc interval should be avoided. Vitamins and minerals may need replacement.

Bulimia nervosa

This refers to episodes of uncontrolled excessive eating, which are also termed 'binges', accompanied by means to lose weight. There is a preoccupation with food and habitual behaviours to avoid the fattening effects of periodic binges. These behaviours include:

- Self-induced vomiting
- Misuse of drugs – laxatives, diuretics, thyroid extract or anorectics.

Additional clinical features include:

- Physical complications of vomiting:
 - a. cardiac arrhythmias
 - b. renal impairment
 - c. muscular paralysis
 - d. tetany – from hypokalaemic alkalosis
 - e. swollen salivary glands – from vomiting
 - f. eroded dental enamel
- Associated psychiatric disorders:
 - a. depressive illness
 - b. alcohol misuse
- Fluctuations in body weight within normal limits
- Menstrual function – periods irregular but amenorrhoea rare
- Personality – perfectionism and/or low self-esteem present premorbidly.

The prevalence of bulimia in community studies is high; it affects between 5% and 30% of girls attending high schools, colleges or universities in the USA. Bulimia is sometimes associated with anorexia nervosa. A premorbid history of dieting is common. The prognosis for bulimia nervosa is better than for anorexia nervosa.

Treatment

Individual cognitive behaviour therapy is more effective than both interpersonal psychotherapy and drug treatments. SSRIs (e.g. fluoxetine) are also an effective treatment, even in the absence of a depressive illness, but may require high doses.

Atypical eating disorders

These include eating disorders that do not conform clinically to the diagnostic criteria for anorexia nervosa or bulimia

Table 23.29 Classification of sexual disorders

Sexual dysfunction	Sexual deviations	Disorders of the gender role
Affecting sexual desire	Variations of the sexual 'object'	Transsexualism
Low libido	Fetishism	
Impaired sexual arousal	Transvestism	
Erectile dysfunction	Paedophilia	
Failure of arousal in women	Bestiality	Transsexualism
Affecting orgasm	Necrophilia	
Premature ejaculation	Variations of the sexual act	
Retarded ejaculation	Exhibitionism	
Orgasmic dysfunction in women	Voyeurism	Transsexualism
	Sadism	
	Masochism	
	Frotteurism	

nervosa. Binge eating disorders consist of bulimia without the vomiting and other weight-reducing strategies.

SEXUAL DISORDERS

Sexual disorders can be divided into sexual dysfunctions and deviations and gender role disorders (Table 23.29).

Sexual dysfunction

Sexual dysfunction in men refers to repeated inability to achieve normal sexual intercourse, whereas in women it refers to a repeatedly unsatisfactory quality of sexual satisfaction. Problems of sexual dysfunction can usefully be classified into those affecting sexual desire, arousal and orgasm. Among men presenting for treatment of sexual dysfunction, erectile dysfunction is the most frequent complaint. The prevalence of premature ejaculation is low, except in young men, while ejaculatory failure is rare.

Sexual drive is affected by constitutional factors, ignorance of sexual technique, anxiety about sexual performance, medical and psychiatric conditions and certain drugs (Tables 23.30, 23.31).

The treatment of sexual dysfunction involves careful assessment of both physical and psychosocial factors, the participation (where appropriate) of the patient's partner, sex education, and specific therapeutic techniques, including relaxation, behavioural therapy and couple therapy. The introduction of phosphodiesterase type 5 inhibitors (e.g. sildenafil) has provided an effective therapy for the treatment of erectile dysfunction (see p. 977).

Sexual deviation

Sexual deviations are regarded as unusual forms of behaviour rather than as an illness. Doctors are only likely to be involved when the behaviour involves breaking the law (e.g. paedophilia) and when there is a question of an associated mental or physical disorder. Men are more likely than women to have sexual deviations.

Gender role disorders

Transsexualism involves a disturbance in gender identity in which the patient is convinced that their body is the wrong

Table 23.30 Medical conditions affecting sexual performance

Endocrine	Diabetes mellitus Hyperthyroidism Hypothyroidism
Cardiovascular	Angina pectoris Previous myocardial infarction Disorders of peripheral circulation
Hepatic	Cirrhosis, particularly alcohol-related
Renal	Chronic kidney disease
Neurological	Neuropathy Spinal cord lesions
Respiratory	Asthma COPD
Psychiatric	Depressive illness Substance misuse

Table 23.31 Drugs affecting sexual arousal

Male arousal	Female arousal
Alcohol ^a	Alcohol ^a
Benzodiazepines	CNS depressants
Neuroleptics	Antidepressants (SSRIs)
Cimetidine	Oral combined
Opiate analgesics	contraceptives
Methyldopa	Methyldopa
Clonidine	Clonidine
Spironolactone	
Antihistamines	
Metoclopramide	
Diuretics	
Beta-blockers	
Cannabis	

^aAlcohol increases the desire but diminishes the performance.

gender. A person's gender identity refers to the individual's sense of masculinity or femininity as distinct from sex. There is increasing evidence that transsexualism is biologically determined, perhaps by prenatal endocrine influences, and functional brain imaging shows specific differences from normal controls.

For males, treatment includes oestrogen administration and, if surgery is to be recommended, a period of living as a woman as a trial beforehand. In the case of female transsexuals, treatment involves surgery and the use of methyltestosterone.

PERSONALITY DISORDERS

These disorders comprise enduring patterns of behaviour which manifest themselves as inflexible responses to a broad range of personal and social situations. Personality disorders are developmental conditions that appear in childhood or adolescence and continue into adult life. Their prevalence is about 15% in the population. They are not secondary to another psychiatric disorder or brain disease, although they may precede or co-exist with other disorders. In contrast, personality change is acquired, usually in adult life, following severe or prolonged stress, extreme environmental deprivation, serious psychiatric disorder or brain injury or disease.

Personality disorders are usually subdivided according to clusters of traits that correspond to the most frequent or obvious behavioural manifestations, but many will show the characteristics of more than one category. The main categories of personality disorder are described in Table 23.32.

Table 23.32	The main categories of personality disorder
Borderline (emotionally unstable)	Act impulsively Intense, short-lived emotional attachments Chronic internal emptiness Frequent self-harm Transient 'pseudo' psychotic features Strong family history of mood disorders
Paranoid	Extreme sensitivity Suspicious Litigious Self-important Preoccupation with conspiracy theories
Schizoid	Emotionally cold and detached Limited capacity to express emotions Indifference to praise or criticism Preference for solitary activities Lack of close friendships Marked insensitivity to social norms
Antisocial	Callous unconcern for the feelings of others Incapacity to maintain enduring relationships Very low tolerance of frustration Incapacity to experience guilt and to learn from experience Tendency to blame others
Histrionic	Self-dramatization, theatricality, suggestibility Shallow and labile emotions Continual seeking for excitement and appreciation Inappropriately seductive appearance and behaviour
Narcissistic	Inflated sense of self-importance Need to be admired Self-referential Arrogant
Anankastic (obsessional)	Feelings of excessive doubt and caution Preoccupation with details, rules and order Perfectionism Excessive conscientiousness, scrupulousness, pedantry and rigidity
Dependent	Encourage others to make their personal decisions Subordinate their needs to others Unwilling to make demands on others Feel unable to care for themselves Preoccupied with fears of being abandoned

Box 23.16 The basis of mental health laws for detention or commitment

1. The individual to be detained must be suffering from a defined mental illness.
2. Detention is for the purposes of observation and refinement of the diagnosis and/or to actively treat the disorder (i.e. detention is a means to an end).
3. Attempts to treat the individual on an outpatient basis have failed.
4. The offer of a voluntary admission to hospital has been refused or is impractical.
5. Treatment in hospital is necessary:
 - because it will benefit the outcome of the illness
 - to protect the patient from harm (in terms of physical health, mental health and abuse or manipulation at the hands of others)
 - to protect others from harm that the patient might cause them passively (neglect) or actively.

INVOLUNTARY DETENTION OR COMMITMENT

Involuntary detention in hospital is typically used as a last resort and treatment on an outpatient basis is preferable in most cases. This describes the practice of *admitting or keeping a patient in hospital against their will*. This is done in compliance with the mental health legislation relevant to the particular country. Application for such a course of action may be made by a doctor (typically but not always a psychiatrist), social worker, psychologist or in some instances, a police officer.

Mental health laws differ between countries and in the case of the USA, also between states. However, in broad terms, the principles remain the same and are summarized in Box 23.16.

The potential for the abuse of such 'powers' is a constant focal point for the review of such legislation. Although this is thankfully uncommon, the detention of individuals as a means to suppress dissent against regimes is well known.

MENTAL CAPACITY ACT

Mental capacity is the ability to make decisions about all aspects of one's life, including but not exclusively healthcare. All doctors need to be able to assess mental capacity. In England and Wales, a new ACT was passed in 2005, which, for the first time, formally protects patients who lack capacity (see Ch. 1, Box 1.4). Some 3% of people in the UK are thought to lack capacity due to conditions affecting brain function, such as dementia. However, the assessment of capacity is specific to an individual decision, so it is possible to have capacity to make one decision but not another. The assessment of capacity is outlined in Box 23.17. Capacity is assumed unless there is evidence to the contrary. In the absence of capacity, the doctor should act in the best interests of the patient and provide the least restrictive management, after consulting an independent advocate.

Box 23.17 Assessment of mental capacity to make a decision

The patient has a demonstrated impairment or disturbance of their mind/brain and a demonstrated inability to do any of the following:

- Understand relevant information
- Retain that information for sufficient time to make the decision
- Use or weigh that information
- Communicate their decision.

Introduction

Skin diseases have a high prevalence throughout the world. In developing countries infectious diseases such as tuberculosis, leprosy and onchocerciasis are common, whereas in developed countries inflammatory disorders such as eczema and acne are common. Skin disorders can be inherited, e.g. Ehlers–Danlos syndrome, a part of normal development, e.g. acne vulgaris, or may present as part of a systemic disorder, e.g. systemic lupus erythematosus (SLE). Approximately 25% of the UK population will develop a skin problem and skin disease accounts for 10% of the workload of family doctors. The common reasons that people with a rash present, are itching or pain, disturbed sleep, anxiety, depression, lack of self-confidence (if rash is obviously visible); and interfering with work (such as allergic hand eczema in a chef, builder or hairdresser).

Rarely, skin disease can be fatal. Examples are malignant melanoma, toxic epidermal necrolysis and pemphigus.

STRUCTURE AND FUNCTION OF THE SKIN

The skin consists of four distinct layers:

1. The epidermis
2. The basement membrane zone

3. The dermis

4. The subcutaneous layer (Fig. 24.1).

The functions of the skin are summarized in Box 24.1.

The epidermis

The epidermis is a stratified epithelium of ectodermal origin that arises from dividing *basal keratinocytes*. The downward projections of the epidermis into the dermis are called the 'rete ridges'. The lower epidermal cells (*basal layer*) produce a variety of keratin filaments and desmosomal proteins (e.g. desmoglein and desmoplakin), which make up the 'cytoskeleton'. This confers strength to the epidermis preventing it shedding. Higher up in the *granular layer*, complex lipids are secreted by the keratinocytes and these form into intercellular lipid bilayers, which act as a semipermeable skin barrier. The upper cells (*stratum corneum*) lose their nuclei and become surrounded by a tough impermeable 'envelope' of various proteins (loricrin, involucrin, filaggrin and keratin). Changes in lipid metabolism and protein expression in the outer layers allow normal shedding of keratinocytes.

Keratinocytes can secrete a variety of cytokines (e.g. interleukins, gamma-interferon, tumour necrosis factor alpha) in response to tissue injury or in certain skin diseases. These play a role in specific immune function, cutaneous inflammation and tissue repair. There is a further layer of protection against microbial invasion – the innate immune system of

Figure 24.1 The structure of the skin (see also Fig. 24.27).

Box 24.1 Functions of the skin

- Physical barrier against friction and shearing forces
- Protection against infection (immune and innate), chemicals, ultraviolet irradiation
- Prevention of excessive water loss or absorption
- Ultraviolet-induced synthesis of vitamin D
- Temperature regulation
- Sensation (pain, touch and temperature)
- Antigen presentation/immunological reactions/wound healing
- Hormonal, e.g. testosterone synthesis

the skin. This comprises neutrophils and macrophages as well as keratinocyte-produced antimicrobial peptides (called β -defensins and cathelicidins). Expression of these peptides is both constitutive and induced by skin inflammation and they are active against infection and play a role in wound healing. A deficiency of these peptides may account for the susceptibility of people with atopic eczema to skin infection.

Other cells in the epidermis

Melanocytes are found in the basal layer and secrete the pigment melanin. These protect against UV irradiation. Racial differences are due to variation in melanin production, not melanocyte numbers.

Merkel cells are also found in the basal layer and originate either from neural crest or epidermal keratinocytes. They are numerous on finger tips and in the oral cavity and play a role in sensation.

Langerhans' cells are dendritic cells found in the supra-basal layer. They derive from the bone marrow and express the cytokine CCR6. They are guided to normal skin, which contains a CCR6 agonist called macrophage inflammatory protein 3 α . Langerhans' cells endocytose extracellular antigens in the skin and then migrate to local lymph nodes for T cell presentation and thus act as antigen-presenting cells.

Basement membrane zone

The basement membrane zone (see Fig. 24.27) is a complex proteinaceous structure consisting of type IV, VII and XVII collagen, hemidesmosomal proteins, integrins and laminin. Collectively, they hold the skin together, keeping the epidermis firmly attached to the dermis. Inherited or autoimmune-induced deficiencies of these proteins can cause skin fragility and a variety of blistering diseases (see p. 1221).

The dermis

The dermis is of mesodermal origin and contains blood and lymphatic vessels, nerves, muscle, appendages (e.g. sweat

glands, sebaceous glands and hair follicles) and a variety of immune cells such as mast cells and lymphocytes. It is a matrix of collagen and elastin in a ground substance.

The sweat glands

Eccrine sweat glands are found throughout the skin except the mucosal surfaces.

Apocrine sweat glands are found in the axillae, anogenital area and scalp and do not function until puberty.

The sweat glands and vasculature are involved in temperature control.

The sebaceous glands

These are inactive until puberty. They are responsible for secreting sebum or grease onto the skin surface (via the hair follicle) and are found in high numbers on the face and scalp.

Nerves

The skin is richly innervated. Nerve fibres enable sensation of touch, pain, itch, vibration and change in temperature.

Hair

Hairs arise from a downgrowth of epidermal keratinocytes into the dermis. The hair shaft has an inner and outer root sheath, a cortex and sometimes a medulla. The lower portion of the hair follicle consists of an expanded bulb (which also contains melanocytes) surrounding a richly innervated and vascularized dermal papilla. The hair regrows from the bulb after shedding. There are three types of hair:

- **Terminal:** medullated coarse hair, e.g. scalp, beard, pubic
- **Vellus:** non-medullated fine downy hairs seen on the face of women and in prepubertal children
- **Lanugo:** non-medullated soft hair on newborns (most marked in premature babies) and occasionally in people with anorexia nervosa.

All hair follicles follow a growth cycle: anagen (growth phase), catagen (involution phase), telogen (shedding phase). At any one time, most hairs (>90%) will be in the anagen phase, which is typically 3–5 years for scalp hair.

Grey hair is due to decreased tyrosinase activity in the hair bulb melanocytes. White hair is due to total loss of these melanocytes.

Nails

Nails are tough plates of hardened keratin, which arise from the nail matrix (just visible as the moon-shaped lunula) under the nail fold. It takes 6 months for a finger-nail to grow out fully and 1 year for a toe-nail.

The subcutaneous layer

The subcutaneous layer consists predominantly of adipose tissue as well as blood vessels and nerves. This layer provides insulation and acts as a lipid store.

APPROACH TO THE PATIENT

The *history* should aim to elicit the following points:

- Time course of rash
- Distribution of lesions
- Symptoms (e.g. itch or pain)
- Family history (especially of atopy and psoriasis)
- Drug/allergy history
- Past medical history

- Provoking factors (e.g. sunlight or diet)
- Previous skin treatments.

Examination entails looking *and* feeling a rash (for terminology, see Table 24.1). It should include an assessment of nails, hair and mucosal surfaces even if these are recorded as unaffected. The following terms are used to describe distribution: flexural, extensor, acral (hands and feet), symmetrical, localized, widespread, facial, unilateral, linear, centripetal (trunk more than limbs), annular and reticulate (lacey network or mesh like).

Investigation. With regard to investigation, clinical acumen remains the most useful tool in dermatology but a variety of tests are useful in confirming a diagnosis (Table 24.2).

INFECTIONS

Bacterial infections (see also p. 114)

The skin's normal bacterial flora prevents colonization by pathogenic organisms. A break in epidermal integrity by trauma, leg ulcers, fungal infections (e.g. athlete's foot) or abnormal scaling of the skin (e.g. in eczema) can allow infection. Nasal carriage of bacteria can be a source of reinfection.

Impetigo

Impetigo is a highly infectious skin disease most common in children (Fig. 24.2). It presents as weeping, exudative areas with a typical honey-coloured crust on the surface. It is spread by direct contact. The term 'scrumpox' refers to impetigo spread between rugby players. Staphylococci or group A β -haemolytic streptococci are the causative agents: skin swabs should be taken.

Prevention

Prevention is by good personal hygiene, particularly hand washing with soap.

Treatment

Impetigo is usually treated with oral antibiotics for 7–10 days (flucloxacillin 500 mg four times daily for *Staphylococcus*; phenoxymethylpenicillin 500 mg four times daily for *Streptococcus*). Other close contacts should be examined and children should avoid school for 1 week after starting therapy. If impetigo appears resistant to treatment or recurrent, take nasal swabs and check other family members. Nasal mupirocin (three times daily for 1 week) is useful to eradicate nasal carriage, especially in hospital staff. Community-acquired MRSA (in chapter 4) is increasingly recognized as a cause of superficial skin infections and treatment should be governed by bacterial sensitivities.

Bullous impetigo/staphylococcal scalded skin syndrome

Rarely *Staphylococcus* releases an exfoliating toxin which acts high up in the epidermis: toxin A causes blistering at the site of infection (bullous impetigo), toxin B spreads through the body causing more widespread blistering (staphylococcal scalded skin syndrome, SSSS). The latter is more common in childhood with very low mortality rates. In adults it is often associated with renal disease or immunosuppression, and mortality rates increase to 50%. Both these toxins cleave desmoglein 1 (a desmosomal protein) so

Table 24.1 Morphological description of skin lesions

Atrophy	Thinning of the skin		Papule	Small palpable, circumscribed lesion (<0.5 cm)	
Bulla	A large fluid-filled blister		Petechia*	Pinpoint-sized macule of blood in the skin	
Crusted	Dried serum or exudate on the skin		Plaque	Large flat-topped, elevated, palpable lesion	
Ecchymosis	Large confluent area of purpura ('bruise')		Purpura	Larger macule or papule of blood in the skin which does not blanch on pressure	
Erosion	Denuded area of skin (partial epidermal loss)		Pustule	Yellowish white pus-filled lesion	
Excoriation	Scratch mark		Scaly	Visible flaking and shedding of surface skin	
Fissure	Deep linear crack or crevice (often in thickened skin)		Telangiectasia	Abnormal visible dilatation of blood vessels	
Lichenified	Thickened epidermis with prominent normal skin markings		Ulcer	Deeper denuded area of skin (full epidermal and dermal loss)	
Macule	Flat, circumscribed non-palpable lesion		Vesicle	A small fluid-filled blister	
Nodule	Large papule (>0.5 cm)		Weal	Itchy raised 'nettle rash'-like swelling due to dermal oedema

Staphylococcal scalded skin syndrome.

mucosal involvement does not occur (this is analogous to pemphigus foliaceus which has the same target antigen, p. 1222).

SSSS can mimic toxic epidermal necrolysis (TEN, see p. 1231). It can be differentiated in two ways: mucosal involvement only occurs in TEN, and skin biopsy shows a more superficial split in SSSS (intraepidermal) than in TEN (subepidermal). Both bullous impetigo and SSSS are treated with anti-staphylococcal antibiotics (e.g. flucloxacillin) and supportive care.

Cellulitis

Cellulitis presents as a hot, sometimes tender area of confluent erythema of the skin due to infection of the deep subcutaneous layer. It often affects the lower leg, causing an upward-spreading, hot erythema, and occasionally will blister, especially if oedema is prominent. It may also be seen affecting one side of the face. Patients are often unwell with a high temperature. It is usually caused by a β -haemolytic streptococcus, rarely a staphylococcus, and sometimes

Table 24.2 Investigations used in skin disorders

Test	Use	Clinical example
Skin swabs	Bacterial culture	Impetigo
Blister fluid	Electron microscopy, viral culture and PCR	Herpes simplex
Skin scrapes	Fungal culture Microscopy	Tinea pedis Scabies
Nail sampling	Fungal culture	Onychomycosis
Wood's light	Fungal fluorescence	Scalp ringworm Erythrasma
Blood tests	Serology Autoantibodies HLA typing DNA analysis	Streptococcal cellulitis Systemic lupus erythematosus Dermatitis herpetiformis Epidermolysis bullosa
Skin biopsy	Histology Immunohistochemistry Immunofluorescence Culture	General diagnosis Cutaneous lymphoma Immunobullous disease Mycobacteria/fungi
Patch tests	Allergic contact eczema	Hand eczema
Urine	Dipstick (glucose) Cytology (red cells)	Diabetes mellitus Vasculitis
Dermatoscopy (direct microscopy of skin)	Assessment of pigmented lesions	Malignant melanoma

Figure 24.2 Impetigo – crusted blistering lesions on the chin.

Figure 24.3 Erythrasma (a) of the axilla; (b) showing pink fluorescence under a Wood's lamp.

community-acquired MRSA (in chapter 4). In the immunosuppressed or diabetic patient Gram-negative organisms or anaerobes should be suspected.

There may be an obvious portal of entry for infection such as a recent abrasion or a venous leg ulcer. The web spaces of the toes should be examined for fungal infection. Skin swabs are usually unhelpful. Confirmation of infection is best done serologically: antistreptolysin O titre (ASOT) and antiDNAse B titre (ADB).

Erysipelas is the term used for a more superficial infection (often on the face) of the dermis and upper subcutaneous layer that clinically presents with a well-defined edge. However, erysipelas and cellulitis overlap so it is often impossible to make a meaningful distinction.

Necrotizing fasciitis (see p. 116).

Treatment

Treatment is with phenoxymethylpenicillin (or erythromycin) and flucloxacillin (all 500 mg four times daily). If disease is widespread, treatment with antibiotics should be given intravenously for 3–5 days followed by at least 2 weeks of oral therapy. It is also necessary to treat any identifiable underlying cause. If cellulitis is recurrent, low-dose antibiotic prophylaxis (e.g. phenoxymethylpenicillin 500 mg twice daily) is used as each episode will cause further lymphatic damage.

Post-cellulitic oedema is common and predisposes to further episodes of cellulitis.

Ecthyma

Ecthyma is also an infection due to *Streptococcus* or *Staphylococcus aureus* or occasionally both. It presents as chronic well-demarcated, deeply ulcerative lesions sometimes with an exudative crust. It is commoner in developing countries, being associated with poor nutrition and hygiene. It is rare in the UK but is seen more commonly in intravenous drug users and people with HIV infection.

Treatment is with phenoxymethylpenicillin and flucloxacillin (both 500 mg four times daily) for 10–14 days.

Erythrasma

Erythrasma is caused by *Corynebacterium minutissimum*. It usually presents as an orange-brown flexural rash, and is often seen in the axillae or toe web spaces (Fig. 24.3). It is frequently misdiagnosed as a fungal infection. The rash shows a dramatic coral pink fluorescence under Wood's (ultraviolet) light.

Treatment is with oral erythromycin 500 mg four times daily for 7–10 days.

FURTHER READING

Jemec GBE. Hidradenitis suppurative. *N Engl J Med* 2012; 366:158–164.

Folliculitis

Folliculitis is an inflammation of the hair follicle. It presents as itchy or tender papules and pustules. *Staphylococcus aureus* is frequently implicated. It is commoner in humid climates and when occlusive clothes are worn. A variant occurs in the beard area (called 'sycosis barbae'), which is commoner in black Africans. This is probably caused by the ability of shaved hair to grow back into the skin, especially if the hair is naturally curly. Extensive, itchy folliculitis of the upper trunk and limbs should alert one to the possibility of underlying HIV infection. Folliculitis following use of hot tubs is due to *Pseudomonas ovale*.

Treatment is with topical antiseptics, topical antibiotics (e.g. sodium fusidate) or oral antibiotics (e.g. flucloxacillin 500 mg or erythromycin 500 mg both four times daily for 2–4 weeks).

Boils (furuncles)

Boils are a rather more deep-seated infection of the skin, often caused by *Staphylococcus*. These can cause painful red swellings. They are commoner in teenagers and often recurrent. Recurrent boils may rarely occur in diabetes mellitus or in immunosuppression. Large boils are sometimes called 'carbuncles'. Swabs should be taken to check antibiotic sensitivity as community-acquired MRSA is an increasingly common cause.

Treatment is with oral antibiotics (e.g. erythromycin 500 mg four times daily for 10–14 days) and occasionally by incision and drainage.

Antiseptics such as chlorhexidine (as soap) can be useful in prophylaxis.

Hidradenitis suppurativa

This condition is characterized by a painful, discharging, chronic inflammation of the skin at sites rich in apocrine glands (axillae, groins, natal cleft). The cause is unknown but it is commoner in females and within some families it appears to be inherited in an autosomal dominant fashion. The initial lesion is occlusion of the hair follicle producing an inflammatory reaction that spreads to the apocrine glands. Clinically it presents after puberty with papules, nodules and abscesses which often progress to cysts and sinus formation. With time, scarring arises. The condition follows a chronic relapsing/remitting course and is worse in obese individuals.

Treatment is difficult but weight loss, 'prophylactic' antibiotics, oral retinoids, zinc and co-cyprindiol (2 mg cyproterone acetate + 35 µg ethinylestradiol in females only) have been tried. They should be used as for acne vulgaris (p. 1212). Severe recalcitrant cases have been treated with intravenous infliximab, a monoclonal antibody (p. 72). Surgery and skin grafting is sometimes required.

Pitted keratolysis

This is a superficial infection of the horny layer of the skin caused by a corynebacterium. It frequently involves the soles of the forefoot and appears as numerous small punched-out circular lesions of a rather macerated skin (e.g. as seen after prolonged immersion). There may be an associated hyperhidrosis of the feet and a prominent odour.

Treatment. Topical antibiotics (e.g. sodium fusidate or clindamycin, applied three times daily for 2–4 weeks) and topical anti-sweating lotions are effective therapies.

Mycobacterial infections

Leprosy (Hansen's disease) (p. 130)

Leprosy usually involves the skin, and the clinical features depend on the body's immune response to the organism *Mycobacterium leprae*.

Indeterminate leprosy is the commonest clinical type, especially in children. This presents as small, hypopigmented or erythematous circular macules with occasional mild anaesthesia and scaling. This may resolve spontaneously or progress to one of the other types. Biopsy reveals a perineural granulomatous infiltrate and scant acid-fast bacilli.

Tuberculoid leprosy presents with a few larger, hypopigmented (see Fig. 4.28) or erythematous plaques with an active erythematous, often raised, rim. Lesions are usually markedly anaesthetic, dry and hairless, reflecting the nerve damage. Nerves may be enlarged and palpable. Biopsy shows a granulomatous infiltrate centred on nerves but no organisms.

Lepromatous leprosy presents with multiple inflammatory papules, plaques and nodules. Loss of the eyebrows ('madarosis') and nasal stuffiness are common. Skin thickening and severe disfigurement may follow. Anaesthesia is much less prominent. Biopsy shows numerous acid-fast bacilli.

Diagnosis and treatment are discussed on page 131.

Skin manifestations of tuberculosis

Tuberculosis can occasionally cause skin manifestations:

- **Lupus vulgaris** usually arises as a post-primary infection. It usually presents on the head or neck with red-brown nodules that look like apple jelly when pressed with a glass slide ('diascopy'). They heal with scarring and new lesions slowly spread out to form a chronic solitary erythematous plaque. Chronic lesions are at high risk of developing squamous cell carcinoma.
- **Tuberculosis verrucosa cutis** arises in people who are partially immune to tuberculosis but who suffer a further direct inoculation in the skin. It presents as warty lesions on a 'cold' erythematous base.
- **Scrofuloderma** arises when an infected lymph node spreads to the skin causing ulceration, scarring and discharge.
- **The tuberculides** are a group of rashes caused by an immune manifestation of tuberculosis rather than direct infection. Erythema nodosum is the commonest and is discussed on page 1216. Erythema induratum ('Bazin's disease') produces similar deep red nodules but these are usually found on the calves rather than the shins and they often ulcerate.

Viral infections

Viral exanthem

This is the commonest type of virus-induced rash and presents clinically as a widespread nonspecific erythematous maculopapular rash. It probably arises due to circulating immune complexes of antibody and viral antigen localizing to dermal blood vessels. The rash can be caused by many different viruses (e.g. echovirus, erythrovirus, human herpes virus-6, Epstein-Barr virus; see chapter 4) and so is rarely diagnostic. The rash will resolve spontaneously in 7–10 days.

Slapped cheek syndrome (erythema infectiosum, fifth disease)

See page 101.

Herpes simplex virus (see also p. 97)

Herpes simplex virus (HSV) occurs as two genomic subtypes. Most people are affected in early childhood with HSV type 1 but the infection is usually subclinical. Occasionally it can present with either clusters of painful blisters on the face or a painful gingivostomatitis. In some individuals cell-mediated immunity is poor and they get recurrent attacks of HSV, often manifest as cold sores. Immunosuppression can also cause a recrudescence of HSV. HSV can also autoinoculate into sites of trauma and present as painful blisters/pustules which may be seen for example on the fingers of healthcare workers ('herpetic whitlow').

HSV type 2 infections are discussed on [page 97](#). Other rare complications of HSV infection include corneal ulceration, eczema herpeticum, chronic perianal ulceration in AIDS patients and erythema multiforme.

Treatment

Oral valaciclovir (500 mg twice daily for 5 days) is used for primary HSV and painful genital HSV. Cold sores are treated with aciclovir cream but this must be used early to be effective in shortening an attack; recurrent sores are treated with oral therapy. Attacks of herpes become less frequent with time. Intravenous aciclovir must be used in immunosuppressed patients.

Varicella zoster virus

Varicella zoster virus (VZV) causes the common childhood infection called chickenpox. It is discussed on [page 98](#). It also causes herpes zoster.

Herpes zoster (shingles)

'Shingles' results from a reactivation of VZV. It may be preceded by a prodromal phase of tingling or pain, which is then followed by a painful and tender blistering eruption in a dermatomal distribution ([Fig. 24.4](#) and [Fig. 4.15](#), p. 98). The blisters occur in crops, may become pustular and then crust over. The rash lasts 2–4 weeks and is usually more severe in the elderly. Occasionally more than one dermatome is involved.

Complications of shingles include severe, persistent pain (post-herpetic neuralgia), ocular disease (if the ophthalmic nerve is involved) and rarely motor neuropathy.

Treatment

Herpes zoster requires adequate analgesia and antibiotics (if secondary bacterial infection is present). Valaciclovir 1 g or famciclovir 250 mg three times daily for 7 days is used, or

Figure 24.4 Herpes zoster in an African male (courtesy of Dr P Matondo, Lusaka, Zambia).

oral aciclovir 800 mg, five times daily for 7 days helps shorten the attack if given early in the illness. Brivudine 125 mg is also available. High-dose intravenous aciclovir is used in immunosuppressed patients. It remains unclear how useful aciclovir therapy is in preventing prolonged post-herpetic neuralgia.

Human papilloma virus

Human papilloma virus (HPV) is responsible for the common cutaneous infection of 'viral warts'.

Common warts are papular lesions with a coarse roughened surface, often seen on the hands and feet, but also on other sites. Small black dots (bleeding points) are often seen within the lesion ([Fig. 24.5](#)). If they occur on the face they are often elongated ('filiform'). Children and adolescents are usually affected. Spread is by direct contact and is also associated with trauma.

Plantar warts (verrucae) is the term used for lesions on the soles of the feet. They often appear flat ('inward growing') although they have the same papillomatous surface change and black dots are often revealed if the skin is pared down (unlike callosities). Warts may be painful or tender if they are over pressure points or around nail folds.

Plane warts are much less common and are caused by certain HPV subtypes. They are clinically different and appear as very small, flesh-coloured or pigmented, flat-topped lesions (best seen with side-on lighting) with little in the way of surface change and no black dots within them. They are usually multiple and are frequently found on the face or the backs of the hands.

Anogenital warts are usually seen in adults and are normally transmitted by sexual contact. They are rare in childhood and, whilst child sex abuse should always be considered, it should be remembered they may well have been transmitted through non-sexual contact. HPV subtypes 16 and 18 are potentially oncogenic and are associated with cervical and anal carcinomas.

Treatment

Common warts on the skin are surprisingly difficult to treat effectively but they almost always resolve spontaneously after months to years (with no scarring), presumably due to cell-mediated immune recognition. When they do resolve, they tend to do so rapidly within a few days.

Regular use of a topical keratolytic agent (e.g. 2–10% salicylic acid) over many months with weekly paring of the lesion helps speed up resolution in some patients and remains the mainstay of treatment. A course of cryotherapy (freezing) can also help. Cautery, surgery, carbon dioxide laser, alpha-interferon injection and bleomycin injection have all been used with variable success but are not recommended, as treatments may be very painful and can cause permanent scarring.

Primary herpes simplex infection.

FURTHER READING

Kim JJ. Focus on research: weighing the benefits and costs of HPV vaccination of young men. *N Engl J Med* 2011; 364:393–395.

Genital warts are usually treated with cryotherapy, trichloroacetic acid, 5% imiquimod cream or topical podophyllin. People with genital warts (and their sexual partners) must be screened for other sexually transmitted diseases.

HPV vaccines against the high-risk oncogenic subtypes (6, 11, 16 and 18) are now available; they should help protect against cervical neoplasia but will have no impact on common warts.

Molluscum contagiosum ('water blisters')

Molluscum contagiosum is a common cutaneous infection of childhood caused by the pox virus. Clinically, lesions are multiple small (1–3 mm) translucent papules which often look like fluid-filled vesicles but are in fact solid. Individual lesions may have a central depression called a punctum. They exhibit the Köbner phenomenon (p. 1208). They can occur at any body site including the genitalia. Transmission is by direct contact. Occasionally lesions may be up to 1 cm in diameter ('giant molluscum').

They usually continue to occur in crops over 6–12 months and rarely require treatment as they spontaneously resolve. Any form of localized trauma, including scratching, helps speed up resolution, and cryotherapy is used in older children. One per cent stabilized hydrogen peroxide cream or 5% imiquimod cream is used in younger children. Molluscum in an adult, especially if giant, should raise the underlying possibility of immunosuppression, especially HIV infection.

Orf

Orf is a disease of sheep (and occasionally goats) due to a pox virus infection. It causes a vesicular and pustular rash around the mouths of young lambs. People who come into contact with the affected fluid may develop lesions on the hands. Clinically these appear as 1–2 cm reddish papules with a surrounding erythema which usually become pustular. The lesion(s) resolves spontaneously after 4–6 weeks and immunity is lifelong. Occasionally, orf is complicated by erythema multiforme.

Fungal infections

Fungal skin disease (mycosis) has a high prevalence in humans with 'thrush' and 'athlete's foot' being two of the commonest examples. In the immunosuppressed, mycoses can be widespread and life-threatening. There are three groups of pathogenic fungi that commonly affect the outer layer of skin or keratinizing epithelium: dermatophytes, *Candida albicans* and pityrosporum.

Dermatophyte infection

By definition, dermatophytes cause a 'ringworm' type of rash. The three main genera responsible are *Trichophyton*, *Microsporum* and *Epidermophyton*. These organisms are identified by microscopy and culture of skin, hair or nail samples. The clinical appearance depends in part on the organism involved, the site affected and the host reaction. All are spread by direct contact from other humans or from infected animals.

Tinea corporis

Ringworm of the body usually presents with asymmetrical, scaly patches which show central clearing and an advancing, scaly, raised edge. Occasionally, vesicles or pustules may be

Figure 24.6 Tinea cruris – ringworm of the groin.

seen in the edge. Central clearing is not a universal feature and it is recommended that all asymmetrical scaly lesions should be scraped for fungus. Ringworm of the face (tinea faciei) often arises after the use of topical steroids. It tends to be more erythematous and less scaly than trunk lesions and it may become itchy after sun exposure.

Tinea cruris

Ringworm of the groin is extremely common worldwide. Early on, the lesions appear as well-demarcated red plaques with an arc-like border extending down the upper thigh (Fig. 24.6). Central clearing may appear and a few pustules or vesicles may be seen if inflammation is intense. Satellite lesions, suggestive of *Candida*, are not present.

Tinea pedis

Athlete's foot may be confined to the toe clefts where the skin looks white, macerated and fissured. It may also be more diffuse, usually causing a diffuse scaly erythema of the soles spreading on to the sides of the foot. Annular lesions are rarely present. There may be an associated hyperhidrosis and fungal involvement of one or more toe-nails. In severe infection a strong inflammatory reaction can occur causing pustules or blistering and this often leads to a misdiagnosis of pompholyx-type eczema.

Tinea manuum

Ringworm of the hands also presents with a diffuse erythematous scaling of the palms with variable skin peeling and skin thickening. Annular lesions are rare at this site.

Tinea capitis

Scalp ringworm infections are common. Fungus may confine itself to within the hair shaft (endothrix) or spread out over the hair surface (ectothrix). The latter can cause fluorescence under a Wood's lamp (ultraviolet light). Scalp ringworm is spread by close contact (especially in schools and households) and may also be spread indirectly by hairdressers. Increase in travel and immigration has allowed the spread of different pathogenic fungi (e.g. *Trichophyton tonsurans* from Central America, *Trichophyton violaceum* from India and Pakistan) into new countries where there is overcrowding and poor social conditions. The majority of UK cases are due to *T. tonsurans* (which does not show fluorescence).

Tinea capitis is much commoner in children, especially those of black African origin whose scalp and hair seems more susceptible to fungal invasion. The clinical appearance of scalp ringworm is highly variable from a mild diffuse scaling with no hair loss (similar to dandruff) to the more typical appearance of circular scaly patches in the scalp with associated alopecia and broken hairs. As the host's

Figure 24.7 Dermatophyte infection of the nail showing white crumbling dystrophy.

immune response increases a few pustules may appear and an exudate may be present. At worst, a full-blown 'kerion' develops; a boggy swollen mass with copious quantities of discharging pus and exudate accompanied by severe alopecia. This is still poorly recognized and inappropriately treated with antibiotics and attempted surgical drainage.

Extensive infection is occasionally accompanied by a widespread papulopustular rash on the trunk. This is a so-called 'id reaction' and probably relates to the host immune response to the fungus. It resolves when the fungal infection is treated.

Tinea unguium

Ringworm of the nails is increasingly common with age and frequently ignored as it is often asymptomatic. Clinically this presents as asymmetrical whitening (or yellowish black discoloration) of one or more nails which usually starts at the distal or lateral edge before spreading throughout the nail (Fig. 24.7). The nail plate appears thickened. Crumbly white material appears under the nail plate and this is the best fungal infections specimen to obtain for mycology sampling. The nail plate may become destroyed with advanced disease.

'Tinea incognito'

This is the term used to describe a fungal skin infection that has been modified by therapy with a topical steroid. The clinical appearance is variable but may show a nonspecific erythema with little in the way of scaling or a few reddish nodules. The history of the rash improving with treatment (owing to the suppression of inflammation) but worsening and spreading every time it is stopped is typical. Skin scrapings for mycology or even a biopsy should confirm the diagnosis.

Treatment

Localized ringworm of the body or flexures is treated with topical antifungal creams (clotrimazole, miconazole, terbinafine or amorolfine applied three times daily for 1–2 weeks). More widespread infection, tinea pedis, tinea manuum and tinea capitis require oral antifungal therapy. Itraconazole (100 mg daily) and terbinafine (250 mg daily) are the most effective drugs used for periods of 1–2 months. High-dose griseofulvin is still used in children for scalp ringworm (15–20 mg/kg per day for 8 weeks).

Tinea unguium of the toe-nails is the most resistant to treatment. Itraconazole (100 mg daily or 200 mg twice daily for 1 week per month 'pulsed therapy') or terbinafine (250 mg daily) given for 3–6 months will cure up to about 80% of cases.

Figure 24.8 Intertrigo with satellite lesions typical of candidiasis.

Candida albicans

Candida albicans (see also p. 170) is a yeast that is sometimes found as part of the body's flora, especially in the gastrointestinal tract. It acts as an opportunist, taking hold in the skin when there is a suitable warm moist environment such as in nappy rash (p. 1234) or intertrigo in obese individuals (Fig. 24.8).

The flexural areas affected are red with a rather ragged peeling edge that may contain a few small pustules. Small circular areas of erythema or small papules and pustules may be seen in front of the advancing edge (satellite lesions).

Candida may also affect the moist interdigital clefts of the toes and mimic tinea pedis. In people who have their hands immersed frequently in water (e.g. cleaners, nurses) *Candida* may cause infection in the macerated skin of the finger web spaces or the damaged skin around the nail folds ('chronic paronychia'). Nail infection may mimic tinea unguium. *Candida* can infect mucosal surfaces of the mouth or genital tract. This tends to occur in patients taking broad-spectrum antibiotics (due to suppression of protective bacterial flora) or in immunosuppressed patients. Clinically, superficial white or creamy pseudomembranous plaques appear which can be scraped off leaving raw areas underneath.

Treatment

Treatment is aimed at removing any underlying predisposing factor and applying topical antifungal creams, e.g. clotrimazole or miconazole (or the equivalent as mouth lozenges/pessaries). *Candida* nail infections require systemic antifungal therapy with an imidazole such as itraconazole (100 mg daily for 3–6 months). Recurrent candidiasis is relatively common, especially in women. Diabetes mellitus should always be excluded. Repeated topical treatment or an oral imidazole may be needed.

Pityrosporum

This yeast occurs as part of the normal flora of human skin. Colonization is prominent in the scalp, flexures and upper trunk. There are two morphological variants, *Pityrosporum ovale* and *Pityrosporum orbiculare*, and the mycelial form of this yeast is called *Malassezia furfur*. *Pityrosporum* can

overgrowth in some individuals and has been implicated in three dermatoses:

- Pityriasis versicolor
- Seborrhoeic eczema (p. 1206)
- *Pityrosporum* folliculitis.

Pityriasis versicolor

This is a relatively common condition of young adults caused by infection with *Pityrosporum*. In white people, it presents most commonly on the trunk with reddish brown scaly macules, which are asymptomatic. In black-skinned individuals (or in whites who are sun-tanned) it more commonly presents as macular areas of hypopigmentation. Inappropriate use of topical steroids tends to spread the rash.

Diagnosis

The diagnosis can be confirmed by skin scrapings or Wood's light examination (yellow fluorescence).

Differential diagnosis includes pityriasis lichenoides chronica, which is a rare condition with recurrent crops of brown scaly papules and erythematous patches. It is seen up to the age of 30 years and can last for years. Treatment is with UVB and topical emollients.

Treatment

Treatment is with selenium sulphide or 2% ketoconazole shampoo (apply to body and remove after 30–60 min and repeat daily for 1 week) or a topical imidazole cream (twice daily for 10 days). Oral itraconazole (100 mg twice daily for 1 week) can be used for resistant cases. The pigmentation takes months to recover even after successful treatment. The condition may recur but can be re-treated.

Pityrosporum folliculitis

This is common in young adult males and characterized by small itchy papules and pustules on the upper back which are centred on hair follicles. It is commoner in people with Down's syndrome. It responds well to ketoconazole shampoo or a topical imidazole cream (twice daily for 2 weeks).

Infestations

Scabies

Scabies is an intensely itchy rash caused by the mite *Sarcoptes scabiei*. It can affect all races and people of any social class. It is most common in children and young adults but can affect any age group. There are 300 million cases of scabies in the world each year. It is commoner in poorer countries with social overcrowding.

Scabies is spread by prolonged close contact such as within households or institutions, and by sexual contact. It presents clinically with itchy red papules (or occasionally vesicles and pustules) which can occur anywhere in the skin but rarely on the face, except in neonates. The distribution of lesions is often suggestive of the diagnosis (Fig. 24.9). Sites of predilection are between the web spaces of the fingers and toes, on the palms and soles, around the wrists and axillae, on the male genitalia, and around the nipples and umbilicus.

The pathognomonic sign is of linear or curved skin burrows but these are not always present. The pruritus is normally worse at night. Excoriations and secondary bacterial infection may complicate the rash. Scabies can be confirmed by taking skin scrapings of a lesion and examining a potassium hydroxide preparation for the mite and/or its eggs by microscopy.

Figure 24.9 Scabies – itchy papules and pustules centred on the web spaces of the hand.

Treatment

A topical scabicide (e.g. 5% permethrin) is applied and washed off after 10 hours. For the treatment to be successful the following factors should be noted:

- All the skin below the neck should be treated, including the genitalia, palms and soles, and under the nails. Treat the head and neck regions in infants (up to age 2 years).
- All close contacts should be treated at the same time even if asymptomatic.
- Reapply scabicide to the hands if they are washed during the treatment period.
- Washing or cleaning of recently worn clothes (preferably at 60°C) is recommended to avoid reinfection.
- Patients should be warned that the pruritus may persist for up to 4 weeks after successful treatment.
- The application should be repeated after 1 week.

Malathion can be used if permethrin is unavailable; benzyl benzoate is used occasionally but is very irritant and should not be used in children. Lindane is a cheap therapy but there are concerns about resistance to this drug and neurotoxicity. Oral ivermectin 200 µg/kg, as 2 doses 2 weeks apart, is as effective as topical therapy and is easy to use.

Crusted scabies (Norwegian scabies)

Crusted scabies is a clinical variant that occurs in immunosuppressed individuals where huge numbers of mites are carried in the skin. Patients are not always itchy but they are extremely infectious after relatively minimal contact, which is unfortunate as the diagnosis is often delayed. Clinically, the condition presents as hyperkeratotic crusted lesions, especially on the hands and feet. Lesions may progress such that the patient has a widespread erythema with irregular crusted plaques. It can therefore mimic infected eczema or psoriasis.

Treatment is with careful barrier nursing, repeated applications of a scabicide and oral ivermectin (200 µg/kg – at least 2 doses 1 week apart).

Lice infection

Lice are blood-sucking ectoparasites that can affect man in three ways.

Crusted scabies in a patient with chronic myeloid leukaemia.

Head lice (*pediculosis capitis*)

Head lice is a common infection worldwide affecting predominantly children and being commoner in females. Spread is by direct contact and encouraged by overcrowding. It usually presents with itch, scalp excoriations and papules on the neck.

Diagnosis can be confirmed by the presence of eggs ('nits') stuck to the hair shaft. Adult lice are seen rarely in heavy infection.

Treatment. Eradication is difficult because of non-compliance as well as resistance patterns. Malathion, carbaryl and phenothrin (two applications 7 days apart with a contact time of 12 hours) are the most commonly used agents. If one treatment fails, a different insecticide is used for the next course in an individual. Treatment is usually repeated after 7 days and metal nit combs may help remove the eggs. In resistant cases high-dose oral ivermectin (400 µg/kg as 2 doses 1 week apart) is used.

Body lice (*pediculosis corporis*)

Infestation with body lice is a disease of poverty and neglect. It is rarely seen in developed countries except in homeless individuals and vagrants. It is spread by direct contact or sharing infested clothing. The lice and eggs are rarely seen on the patient but are commonly found on the clothing. It presents with itch, excoriations and sometimes post-inflammatory hyperpigmentation of the skin.

Treatment consists of malathion or permethrin for the patient and high-temperature washing and drying of clothing.

Pubic lice (crabs, *phthiriasis pubis*) (p. 160)

Pubic lice are transmitted by direct contact, usually sexual. Infestation presents with itching, especially at night. Lice can be seen near the base of the hair with eggs somewhat further up the shaft. Occasionally eyebrows, eyelashes and the beard area are affected.

Treatment is as for head lice but all sexual contacts should be treated and other sexually transmitted diseases should be screened for. Pubic lice of the eyelashes is treated with white soft paraffin three times daily for 1–2 weeks.

Arthropod-borne diseases ('insect bites' or papular urticaria)

These depend on contact with an animal (e.g. dog, cat, bird) that is infested with fleas (*Cheyletiella*) or on bites from flying insects (e.g. midges, mosquitoes). In the case of flea bites the animal itself may be itchy with scaly and thickened skin. These fleas can also live in soft furnishings (e.g. carpets and beds) even after the animal has been removed. Bites present as itchy urticated lesions, which are often grouped in clusters. The legs are most commonly affected. It is not unusual for an individual to react badly to bites when other family members seem unaffected. Anti-flea treatment of the animal and furnishings is required. Insect repellents and appropriate clothing help lessen bites from flying insects.

Infestations with bed bugs have increased enormously in the past decade in the developed world. They can be seen as small brown/black lentil-sized insects at night-time as they are attracted to warmth and carbon dioxide of sleeping humans. Infestations require professional insecticide treatments of properties. Advice can be obtained from the National Pest Technicians Association (www.npta.org.uk).

Table 24.3 Classification of eczema

Endogenous	Exogenous

Venous ('gravitational') eczema	prurigo
Asteatotic eczema	

PAPULO-SQUAMOUS/INFLAMMATORY RASHES

Eczema

Introduction

Eczema is synonymous with the term dermatitis and the two words are interchangeable. In the developed world, eczema accounts for a large proportion of skin disease. It is estimated that 10% of people have some form of eczema at any one time, and up to 40% of the population will have an episode of eczema during their lifetime.

All eczemas (Table 24.3) have some features in common and there is a spectrum of clinical presentation from acute through to chronic. Vesicles or bullae may appear in the acute stage if inflammation is intense. In subacute eczema the skin can be erythematous, dry and flaky, oedematous and crusted (especially if secondarily infected). Chronic persistent eczema is characterized by thickened or lichenified skin. Eczema is nearly always itchy. Histologically 'eczematous change' refers to a collection of fluid in the epidermis between the keratinocytes ('spongiosis') and an upper dermal perivascular infiltrate of lymphohistiocytic cells. In more chronic disease there is marked thickening of the epidermis ('acanthosis').

Atopic eczema

This type of eczema ('endogenous eczema') occurs in individuals who are 'atopic' (p. 823). It is common, occurring in up to 5% of the UK population. It is commoner in early life, occurring at some stage during childhood in up to 10–20% of all children.

Aetiology

The exact pathophysiology is not fully understood but there is an initial selective activation of Th2-type CD4 lymphocytes in the skin which drives the inflammatory process. This precedes the chronic phase when Th0 and Th1 cells predominate. In at least 80% of cases there is a raised serum total IgE level. Atopic eczema is a genetically complex, familial disease with a strong maternal influence. A positive family history of atopic disease is often present: there is a 90% concordance in monozygotic twins but only 20% in dizygotic twins. If one parent has atopic disease, the risk for a child of developing eczema is about 20–30%. If both parents have atopic eczema the risk is greater than 50%.

Studies have shown abnormal skin-homing T cells in eczema compared to controls. Genetic research points towards a primary problem of skin barrier function, suggesting the above immunological changes are secondary. Loss-of-function mutations in the epidermal barrier protein filaggrin cause ichthyosis vulgaris but can predispose to atopic eczema in Caucasian individuals. Different mutations in the same gene have been found in Japanese people with

Papulo-squamous/inflammatory rashes

Eczema herpeticum showing multiple punched-out crusted erosions.

eczema. *Filaggrin* is coded by *FLG* gene in the epidermal differentiation complex on chromosome 1q21. Very strong linkage to this region would suggest that other genes in this area are also involved in the development of atopic eczema (e.g. loricrin, involucrin, S100 calcium-binding proteins). Linkage is also found to 3q21, 3p22–24, 17q25, 20p. Other candidate genes include *SPINK 5* (a serine protease inhibitor), mast cell chymotrypsin and peptidoglycan recognition proteins.

Exacerbating factors

Infection either in the skin or systemically can lead to an exacerbation, possibly by a superantigen effect. Paradoxically, lack of infection (in infancy) may cause the immune system to follow a Th2 pathway and allow eczema to develop (the so-called 'hygiene hypothesis'). Strong detergents, chemicals and even woollen clothes can be irritant and exacerbate eczema. Teething is another factor in young children. Severe anxiety or stress appears to exacerbate eczema in some individuals. Cat and dog fur can certainly make eczema worse, possibly by both allergic and irritant mechanisms. The role of house dust mites and diet is less clear cut. There is some evidence that food allergens may play a role in triggering atopic eczema and that dairy products or eggs cause exacerbation of eczema in a few infants under 12 months of age.

Clinical features

Atopic eczema can present as a number of distinct morphological variants. The commonest presentation is of itchy erythematous scaly patches, especially in the flexures such as in front of the elbows and ankles, behind the knees (Fig. 24.10) and around the neck. In infants eczema often starts on the face before spreading to the body. Very acute lesions may weep or exude and can show small vesicles. Scratching can produce excoriations, and repeated rubbing produces skin thickening (lichenification) with exaggerated skin markings.

In people with pigmented skin, eczema often shows a reverse pattern of extensor involvement. Also the eczema may be papular or follicular in nature, and lichenification is common. A final problem in pigmented skin is of post-inflammatory hyper- or hypopigmentation which is often very slow to fade after control of the eczema.

Associated features

In some atopic individuals, the skin of the upper arms and thighs may feel roughened due to follicular hyperkeratosis ('keratosis pilaris'). The palms may show very prominent skin creases ('hyperlinear palms'). There may be an associated dry 'fish-like' scaling of the skin which is non-inflammatory and often prominent on the lower legs ('ichthyosis vulgaris').

Figure 24.10 Atopic eczema behind the knees.

Complications

Broken skin commonly becomes secondarily infected by bacteria, usually *Staphylococcus aureus*, although streptococci can colonize eczema, especially in macerated flexural areas such as the neck and groin. Clinically, this infection may appear as crusted, weeping impetigo-like lesions. Cutaneous viral infections (e.g. viral warts and molluscum) are often widespread in atopic eczema and are probably spread by scratching. HSV can cause a widespread eruption called eczema herpeticum (Kaposi's varicelliform eruption). This can occasionally be a very severe infection and rarely can be fatal. It appears as multiple small blisters or punched-out crusted lesions associated with malaise and pyrexia, and needs rapid treatment with oral (or intravenous if severe) aciclovir. Ocular complications of atopic eczema include conjunctival irritation and less commonly keratoconjunctivitis and cataract. Retarded growth may be seen in children with chronic severe eczema; it is due to the disease itself and not the use of topical steroids.

Investigations

The diagnosis of atopic eczema is clinical. However atopy is characterized by high serum IgE levels or high specific IgE levels to certain ingested or inhaled antigens and a blood eosinophilia in about 80% of cases.

Prognosis

The majority (80–90%) of children with early-onset atopic eczema will spontaneously improve and 'clear' before the teenage years, 50% being clear by the age of 6. A few will get a recurrence as adults, even if just as hand eczema. However, if the onset of eczema is late in childhood or in adulthood, the disorder follows a more chronic remitting/relapsing course.

Treatment (Box 24.2)**General measures**

These include avoiding known irritants (especially soaps or furry animals), wearing cotton clothes, and not getting too hot. Manipulating the diet (e.g. dairy-free diet) is rarely beneficial except in a few children, especially those under 12 months of age where cows milk and egg allergy are common. Any change in diet should be made under supervision, especially with growing children who may need supplements such as calcium.

Topical therapies

Topical therapies (p. 1235) are sufficient to control atopic eczema in most people. The 'triple' combination of topical steroid, frequent emollients (see Table 24.18) and bath oil and soap substitute (e.g. aqueous cream) helps.

**Box 24.2 Management of atopic eczema**

- Education and explanation
- Avoidance of irritants/allergens
- Emollients
- Bath oils/soap substitutes
- Topical therapies:
 - steroids
 - immunomodulators
- Adjunct therapies:
 - oral antibiotics
 - sedating antihistamines
 - bandaging
- Phototherapy
- Systemic therapy, e.g. oral prednisolone, ciclosporin

Table 24.4 Classification of topical steroids by potency

Very potent	0.05% clobetasol propionate 0.3% diflucortolone valerate
Potent	0.1% betamethasone valerate 0.025% fluocinolone acetonide
Diluted potent	0.025% betamethasone valerate 0.00625% fluocinolone acetonide
Moderately potent	0.05% clobetasone butyrate 0.05% alclometasone dipropionate
Mild	2.5% hydrocortisone 1% hydrocortisone

Written information or a practical demonstration of how to apply these treatments improves compliance.

Use of topical steroids. Unjustified fear about the dangers of topical steroids has often led to undertreatment of eczema. Providing appropriate-strength steroid preparations are used for the right body site, these compounds can be used quite safely on a long-term intermittent basis. Topical steroids can be divided into five groups depending on their potency (Table 24.4).

The following guidelines should be followed to allow their safe use in common chronic inflammatory skin conditions.

- The face should be treated only with mild steroids.
- In adults the body should be treated with either mild, moderately potent or diluted potent steroids.
- In young children the body should be treated with mild and moderately potent steroids.
- Potent steroids are used for short courses (7–10 days).
- Treatment of the palms and soles (but not the dorsal surfaces) may require potent or very potent steroids as the skin is much thicker.
- Regular use of emollients may lessen the need for steroid use.
- Only use steroids on inflamed skin. Do not use as an emollient.
- 'Apply sparingly' means use sufficient to leave a glistening surface to the skin after application.
- Use weaker steroid preparations in flexures (e.g. the groin, and under breasts) as apposition of the skin at these sites tends to occlude the treatment and increase absorption.

Topical immunomodulators

Tacrolimus ointment (0.1% and 0.03%) and the less potent pimecrolimus cream can be used for atopic eczema in patients over 2 years old. They have the advantage over potent steroids of not causing skin atrophy and are thus very useful for treating sensitive areas such as the face and eyelids. They can be irritant when first used (although this settles with continued use) and 9% of patients develop flushing after alcohol. The long-term side-effects remain unknown but there have been no major problems. They do not work so well on lichenified eczema, probably due to poor absorption. Current advice is to avoid vaccinations and sun exposure when using these agents. The milder potency steroid creams are still first-line therapy but tacrolimus is a useful alternative to excessive use of potent steroids. Tacrolimus ointment is also used twice weekly to prevent eczema flares.

Antibiotics

These are needed for bacterial infection and are usually given orally for 7–10 days. Flucloxacillin (500 mg four times daily)

is effective against *Staphylococcus* and phenoxymethylpenicillin (500 mg four times daily) acts against *Streptococcus*. Erythromycin (500 mg four times daily) is useful if there is allergy to penicillin. Topical antiseptics are used in cases of recurrent infection but they can be irritant. They are usually added to the bath water rather than applied directly to the skin.

Sedating antihistamines

These (e.g. oral hydroxyzine hydrochloride 10–25 mg) are useful at night-time.

Bandaging

Paste bandaging can be useful for resistant or lichenified eczema of the limbs. It helps absorption of treatment and acts as a barrier to prevent scratching. Wet tubular gauze bandages are used for inpatient therapy but are difficult and time-consuming to use at home.

Second-line agents

These are used in severe non-responsive cases, especially if the eczema is significantly interfering with an individual's life (e.g. growth, sleeping, schoolwork or job). Ultraviolet phototherapy (see p. 1215), prednisolone (initial doses up to 30 mg daily), ciclosporin (3–5 mg/kg daily) and azathioprine (1–3 mg/kg daily) (in chapter 6) can all be effective treatments. However they all have side-effects and the risk/benefit ratio must be openly discussed with the patient before they are used.

Use of ciclosporin. Ciclosporin is a selective immunosuppressant that inhibits interleukin-2 production by T lymphocytes. A large number of other drugs interact with ciclosporin (e.g. erythromycin, NSAIDs) and should be avoided. Renal damage and hypertension are the two most serious side-effects so blood pressure, serum creatinine and estimated glomerular filtration rate (eGFR) should be measured every 6–12 weeks. Renal damage becomes increasingly common with time and tends to be dose-dependent but is mostly reversible. Hypertrichosis, paraesthesia and nausea are less serious side-effects. Pregnancy should be avoided.

Discoid eczema (nummular eczema)

Discoid eczema is a morphological variant of eczema characterized by well-demarcated scaly patches, especially on the limbs, and this can be confused sometimes with psoriasis. It is commoner in adults and can occur in both atopic and non-atopic individuals. It tends to follow an acute/sub-acute course rather than a chronic pattern. There is often an infective component (*Staphylococcus aureus*).

Hand eczema

Eczema may be confined to the hands (and feet). It can present with:

- itchy vesicles or blisters on the palm and along the sides of the fingers (also called 'pompholyx') (Fig. 24.11)
- a diffuse erythematous scaling and hyperkeratosis of the palms
- a scaling and peeling, most marked at the finger tips.

Hand eczema is not unusual in atopics but more frequently occurs in non-atopic individuals, and a cause is not always found. A history of contact with irritants (e.g. detergents, chemicals) and an occupational history should be sought, especially in finger-tip eczema. Patch testing for specific allergic or contact eczema should always be performed as up to 10% of individuals with hand eczema will show a positive test. Finally, look for evidence of fungal infection as this

Figure 24.12 Seborrheic eczema affecting the sides of the nose.

can occasionally induce a secondary pompholyx of the hands or feet (a so-called 'id reaction').

Seborrheic eczema

Aetiology

Overgrowth of *Pityrosporum ovale* (also called *Malassezia furfur* in its hyphal form) together with a strong cutaneous immune response to this yeast produces the characteristic inflammation and scaling of seborrheic eczema. The condition is more common in Parkinsonism as well as in HIV disease.

Clinical features

Seborrheic eczema affects body sites rich in sebaceous glands, although these do not appear to be causal. Three age groups are affected:

- **In neonates** it is common and presents as yellowish thick crusts on the scalp (cradle cap). A more widespread erythematous, scaly rash can be seen over the trunk, especially affecting the nappy area. Unlike with atopic eczema, the child is normally unbothered as there is little associated pruritus. The rash normally improves spontaneously after a few weeks.
- **In young adults** (especially males) it occurs in 1–3% of the population. The rash is more persistent and presents as an erythematous scaling along the sides of the nose (Fig. 24.12), in the eyebrows, around the eyes and extending into the scalp (which shows marked dandruff). It may affect the skin over the sternum, axillae and

groins, and the glans penis. A blepharitis may also be present.

- **In elderly people** seborrheic eczema can be more severe and progress to involve large areas of the body and even cause erythroderma.

Treatment

This is suppressive rather than curative. A combination of a mild steroid ointment (e.g. 1% hydrocortisone applied twice daily) and a topical antifungal cream (e.g. miconazole cream applied twice daily) will help to control the eruption. Topical 0.1% tacrolimus ointment or pimecrolimus cream can also be used.

Ketoconazole shampoo and arachis oil are useful for the scalp. Emollients and a soap substitute are useful adjuncts.

Venous eczema (varicose eczema, gravitational eczema)

This type of eczema occurs on the lower legs due to chronic venous hypertension (usually of more than 2 years' duration) (see p. 1226).

Clinical features

Venous eczema tends to occur in older people, especially women. It usually appears on the lower legs around the ankles. There may be a past history of venous thrombosis or previous surgery for varicose veins. Brownish pigmentation (haemosiderin) may be seen in the skin and a venous leg ulcer or varicose veins may be present.

Superimposed contact eczema is common in venous eczema patients, especially when there have been chronic venous leg ulcers. This is usually due to an allergic reaction to topical therapies or skin dressings. Patch testing should always be done in treatment-resistant cases.

Treatment

This should include emollients and a moderately potent topical steroid. Support stockings or compression bandages, together with leg elevation, help decrease the underlying venous hypertension (p. 1226).

Asteatotic eczema (winter eczema, eczema craquelé, senile eczema)

This is a dry plate-like cracking of the skin with a red, eczematous component, which occurs in elderly people. It occurs predominantly on the lower legs and the backs of the hands, especially in winter. The exact cause is unknown but the repeated use of soaps in the elderly with the loss of the stratum corneum lipids with age is probably involved. Rarely asteatotic eczema can be the presenting sign of hypothyroidism or can follow the commencement of diuretic therapy.

Treatment

Avoidance of soaps, and the regular use of emollients and bath oils should be encouraged. If the skin is very inflamed, a mild topical steroid can be used.

Allergic contact and irritant contact eczema

If the eczema is in an unusual or localized distribution (Fig. 24.13), especially if there is no personal or family history of atopic disease, one of a variety of environmental agents (exogenous eczema) is the likely cause. A history of an exacerbation of eczema at the workplace is also suggestive

Figure 24.13 Contact eczema secondary to perfume allergy.

('occupational dermatitis'). There are two possible mechanisms: direct irritation or an allergic reaction (type IV delayed hypersensitivity). A detailed history of occupation, hobbies, cosmetic products, clothing and contact with chemicals is necessary.

Allergic contact eczema occurs after repeated exposure to a chemical substance but only in those people who are susceptible to develop an allergic reaction. It is common, occurring in up to 4% of some populations. Many substances can cause this type of reaction but the commoner culprits are nickel (in costume jewellery and buckles); chromate (in cement); latex (in surgical gloves); perfume (in cosmetics and air fresheners); and plants (such as primula or compositae). A good history is necessary and if suspicious, patch testing should be arranged to prove any allergy.

Irritant contact eczema can occur in any individual. It often occurs on the hands after repeated exposures to irritants such as detergents, soaps or bleach. It is therefore common in housewives, cleaners, hairdressers, mechanics and nurses.

Treatment

Treatment is as for atopic eczema as well as strict avoidance of any causative agent. This may also involve wearing of protective clothing such as gloves or in extreme cases even changing occupation or hobbies.

Photosensitive eczema

This is discussed on [page 1215](#).

Lichen simplex/nodular prurigo (neurodermatitis)

These terms are applied to a disorder characterized by chronic scratching or rubbing in the absence of an underlying dermatosis. They are more common in Asians and also in black African and Oriental patients.

Lichen simplex appears as thickened, scaly and hyperpigmented areas of lichenification ([Fig. 24.14](#)). It starts with intense itching that becomes tender with increased rubbing or scratching, and a self-perpetuating 'itch-scratch cycle' develops. It is rare before adolescence and is commoner in females. Common sites are the nape of the neck, the lateral calves, the upper thighs, the upper back and the scrotum or vulva but any accessible site can be affected.

Nodular prurigo is a different pattern of cutaneous response to scratching, rubbing or picking. Individual, itchy papules and domed nodules appear, especially on the upper trunk and the extensor surfaces of the limbs. They show

Figure 24.14 Lichen simplex from chronic rubbing.

significant surface damage from scratching. This is a chronic unremitting condition, which is often resistant to treatment.

These two conditions overlap, with some patients showing mixed features. Atopic individuals seem predisposed to develop these conditions (in the absence of obviously active eczema). However, they can occur in non-atopics. Emotional stress appears to be a contributory factor in many of these patients (hence the name neurodermatitis).

The diagnosis is made by exclusion of other pathologies and may require a skin biopsy. General medical causes of pruritus should be excluded including HIV infection ([p. 154](#) and [p. 177](#)). In the elderly, nodular prurigo may be an early sign of bullous pemphigoid, before the more typical blistering phase has appeared.

Treatment

Treatment is often difficult as symptoms can be intractable. Very potent topical steroids (e.g. 0.05% clobetasol propionate) with occlusive tar bandaging may sometimes help. Intralesional steroids can also be useful but there is a risk of atrophy. For resistant cases (especially of prurigo lesions) topical doxepin, phototherapy ([p. 1215](#)), low-dose oral amitriptyline (50 mg nightly) and ciclosporin (3–5 mg/kg per day) are used.

Psoriasis

Psoriasis is a common papulo-squamous disorder affecting 2% of the population and is characterized by well-demarcated, red scaly plaques. The skin becomes inflamed and hyperproliferates at about ten times the normal rate. It affects males and females equally and can affect all races. The age of onset occurs in two peaks. Early onset (age 16–22) is commoner and is often associated with a positive family history. Late-onset disease peaks at age 55–60 years.

Aetiology

The condition appears to be polygenic but is also dependent on certain environmental triggers. Twin studies show 73% concordance in monozygotic twins compared with 20% in dizygotic pairs. Nine genetic psoriasis susceptibility loci have been identified (PSORS 1–9). Some loci seem shared with other diseases: atopic eczema (1q21, 3q21, 17q25, 20p), rheumatoid arthritis (3q21, 17q24–25) and Crohn's disease (16). The most studied locus, PSORS1 (which accounts for 35–50% of the heritable component), lies in the MHC region of chromosome 6 (HLA Cw6).

The exact aetiology is unknown but evidence suggests that psoriasis is a T-lymphocyte-driven disorder to an

Figure 24.15 Pathogenesis of psoriasis. Trigger factors activate the dendritic cell which, in turn, Th1 and Th17 T cell via IL-12 and IL-23. These T cells secrete mediators to activate keratinocytes to produce antimicrobial peptides, cytokines and chemokines. These maintain the inflammation and feedback to activate the dendritic cell. [A], Site of action of ustekinumab, brikinumab. [B], Infliximab, etanercept, adalimumab.

unidentified antigen(s). Figure 24.15 shows the trigger factors that activate the antigen-presenting cell (dendritic/Langerhans). This activation results in upregulation of Th1-type T cell cytokines, e.g. interferon- γ , interleukins (IL-1, -2, -8), growth factors (TGF- α and TNF- α) and adhesion molecules (ICAM-1). The pro-inflammatory cytokine TNF- α is also produced by keratinocytes and this may be involved in both initiation and maintenance of psoriatic lesions. TNF- α blocking drugs have proved highly effective in treatment (Fig. 24.15). IL-17 and IL-22 are thought to work together to produce clinical psoriasis (see p. 1210).

Pathology

Skin biopsy shows epidermal acanthosis and parakeratosis, reflecting the increase in skin turnover, and the granular layer is often absent. Polymorphonuclear abscesses may be seen in the upper epidermis. The epidermal rete ridges appear elongated and clubbed as they fold down into the dermis. Dermal changes include capillary dilation surrounded by a mixed neutrophilic and lymphohistiocytic perivascular infiltrate.

Clinical features

Psoriasis can present in different clinical patterns but there is overlap between the different forms. Certain drugs can make psoriasis worse, notably lithium, antimalarials and rarely beta-blockers.

Chronic plaque psoriasis

This is the 'common' type of psoriasis. It is characterized by pinkish red scaly plaques, with a silver scale seen, especially on extensor surfaces such as knees (Fig. 24.16a) and elbows. The lower back, ears and scalp are also commonly involved. New plaques of psoriasis occur at sites of skin trauma – the so-called 'Köbner phenomenon'. The lesions can become itchy or sore.

a

b

Figure 24.16 (a) Psoriasis of the knees. **(b)** Guttate psoriasis in an African patient (courtesy of Dr P Matondo, Lusaka, Zambia).

Chronic plaque psoriasis on elbows in an Indian patient.

Flexural psoriasis

This tends to occur in later life. It is characterized by well-demarcated, red glazed plaques confined to flexures such as the groin, natal cleft and sub-mammary area. As these sites are apposed, there is rarely any scaling. In the absence of psoriasis elsewhere the rash is often misdiagnosed as candida intertrigo but the latter will normally show satellite lesions.

Guttate psoriasis

'Raindrop-like' psoriasis is a variant most commonly seen in children and young adults (Fig. 24.16b). An explosive eruption of very small circular or oval plaques appears over the trunk about 2 weeks after a streptococcal sore throat.

Erythrodermic and pustular psoriasis

These are the most severe types of psoriasis reflecting a widespread intense inflammation of the skin. They can occur together ('Von Zumbusch' psoriasis) and may be associated with malaise, pyrexia and circulatory disturbance. This form can be life-threatening. The pustules are not infected but are sterile collections of inflammatory cells. There is also a more localized variant of pustular psoriasis that confines itself to the hands and feet (palmo-plantar psoriasis) but is not associated with severe systemic symptoms. This latter type is more common in heavy cigarette smokers.

Associated features

Nails. Up to 50% of individuals with psoriasis develop nail changes (Fig. 24.17) and rarely these can precede the onset of skin disease. There are five types of nail change: (a) pitting of the nail plate; (b) distal separation of the nail plate (onycholysis); (c) yellow-brown discoloration; (d) subungual hyperkeratosis; (e) rarely a damaged nail matrix and lost nail plate. Treatment of nail dystrophy is very difficult.

Arthritis. Some 5–10% of individuals develop psoriatic arthritis and most of these will have nail changes (p. 602).

Treatment

This is concerned with control rather than cure and should be tailored to the patient's wishes (Box 24.3). Severe cases may require hospitalization.

Chronic plaque psoriasis: emollients should always be used to hydrate the skin. Mild to moderate topical steroids, synthetic vitamin D3 analogues (e.g. calcipotriol, calcitriol, tacalcitol), 0.05% tazarotene (a retinoid) and purified coal tar are the most popular therapies. Salicylic acid can be a useful adjunct. All should be applied once to twice daily to palpable lesions. Once lesions have flattened, therapy can be discontinued. Tazarotene and calcipotriol can be very irritant

(calcitriol somewhat less so) so they are often used in combination with steroid creams. Vitamin D analogues should be used with caution in extensive psoriasis because there is a risk of hypercalcaemia if greater than 100 g is used per week.

Dithranol causes staining of the skin and clothing and is more difficult to use at home on a regular basis. It is normally applied for 20–60 min and then washed off. It must be applied carefully to the lesions as it causes irritation to normal skin. Dithranol is more likely to induce remission than other therapies but is being recommended less because of poor compliance.

Topical therapies are sometimes used in combination with UVB or PUVA. The 'Goeckerman regimen' consists of tar and UVB; the 'Ingram regimen' consists of dithranol and UVB. The latter has similar results to oral PUVA in terms of clearance rates and lengths of remission – approximately 75% in 6 weeks.

Flexural psoriasis is usually treated with mild steroid and/or tar topical creams. Calcitriol and 0.1% tacrolimus ointment are also useful for treating flexural (facial and genital) psoriasis where irritation can be a problem.

Guttate psoriasis is usually treated with topical therapies and/or UVB phototherapy.

Palmo-plantar psoriasis is treated with very potent topical steroids, coal tar paste or local hand and foot PUVA.

Systemic therapy. Agents such as methotrexate, acitretin, mycophenolate, ciclosporin or hydroxycarbamide (hydroxy-urea) are used for resistant cases.

Erythrodermic psoriasis also requires systemic therapy (but not phototherapy) as well as general supportive measures (p. 1215).

All systemic treatments must be monitored for toxicity.

Use of methotrexate. Methotrexate is normally given once weekly. Some patients experience severe nausea on the day they take it which can be lessened by folic acid therapy. Both men and women should avoid conception during and for 3 months after therapy. Some patients are allergic to methotrexate and develop a pyrexia and mouth ulceration. Regular blood tests need to be done to monitor for bone marrow suppression and liver damage. Alcohol must be avoided as this increases the risk of hepatotoxicity. NSAIDs should also be avoided as these inhibit excretion. Lower doses should be used in the elderly. Long-term use causes hepatic fibrosis, and regular monitoring of patients' serum procollagen III peptide level or elastography (p. 327) is being used to assess fibrosis development. People with concomitant psoriatic arthritis are more likely to develop pulmonary fibrosis.

Figure 24.17 Psoriasis of the nail – yellowish brown discoloration and distal nail plate separation (onycholysis).

Box 24.3 Management of psoriasis

- Education and explanation
- Emollients
- Topical therapies:
 - Mild to moderate steroids
 - Vitamin D analogues
 - Tazarotene
 - Tacrolimus
 - Purified coal tar
 - Salicylic acid
 - Dithranol
- Topical therapy in combination with UVB or PUVA
- Systemic therapy if conventional treatments have failed (monitoring for toxicity is required):
 - Methotrexate
 - Ciclosporin
 - Mycophenolate
 - Hydroxycarbamide
 - Acitretin
- Cytokine modulators if systemic therapy has failed:
 - Etanercept
 - Adalimumab
 - Infliximab
 - Ustekinumab

Cytokine modulators (see Fig. 24.15)

Cytokine modulators are at present only used in patients who have severe disease who have failed (or cannot tolerate due to toxicity) conventional systemic treatments.

- Etanercept, infliximab and adalimumab (TNF- α blockers) are highly effective and tend to be used first-line in the UK as they have the longest safety data.
- Ustekinumab (a human interleukin-12/23 monoclonal antibody) is highly effective. Its safety data is limited so it is most commonly used in those patients that fail a TNF- α blocker.
- Alefacept (a dimeric fusion protein that blocks LFA-3/CD2 interaction on T cells) is somewhat less effective and has been licensed for use in North America and Australia but not Europe. CD4 counts must be checked during therapy.
- Brikinumab, a monoclonal antibody against the p40 molecule shared by IL-12 and IL-23, is effective in moderate and severe psoriasis.
- Brodalumab (an anti-IL-17 receptor antibody) and ixekizumab (an anti-IL-17 monoclonal antibody) have recently been shown to be effective in psoriasis.

All these agents are given by injection and are very expensive. Long-term side-effects of these new agents are unknown. TNF- α blockers' side-effects are discussed on page 524. One biologic drug (efalizumab) has been withdrawn due to the risk of prion brain disease.

Prognosis

Most individuals who develop chronic plaque psoriasis will have the condition lifelong but 80% will get a remission at times. It fluctuates in severity and there are no available tests to predict outcome. Guttate psoriasis resolves spontaneously and in up to a third of individuals does not recur. However, two-thirds will go on to get recurrent guttate attacks or will progress to chronic plaque psoriasis.

Urticaria and angio-oedema

Urticaria (hives, 'nettle rash') is a common skin condition characterized by the acute development of itchy wheals or swellings in the skin due to leaky dermal vessels (Fig. 24.18). Angio-oedema is a similar condition but involves sub-dermal vessels.

Aetiology

The final event in pathogenesis involves degranulation of cutaneous mast cells which releases a number of inflammatory mediators (including histamine) which in turn make the

dermal and sub-dermal capillaries leaky. In most cases the underlying cause is autoimmune (patients develop autoantibodies against the high-affinity IgE receptor α -subunit of the mast cell). Occasionally urticaria is secondary to viral or parasitic infection, drug reactions (e.g. NSAIDs, penicillin, ACE inhibitors, opiates), food allergy (e.g. to strawberries, food colourings or seafood), or rarely systemic lupus erythematosus. Urticaria/angio-oedema is commoner in atopic individuals and usually presents in children and young adults.

In hereditary angio-oedema and ACE inhibitor induced angio-oedema, bradykinin (a potent vasodilator) is one of the key mediators (not histamine) and this observation has led to some new drug developments.

Clinical features

Urticaria produces cutaneous swellings or wheals developing acutely over a few minutes. They can occur anywhere on the skin and last between minutes and hours before resolving spontaneously. Lesions are intensely itchy and show no surface change or scaling. They are normally erythematous but if very acutely swollen, they may appear flesh-coloured or whitish and people often mistake them for blisters.

Angio-oedema with subcutaneous involvement presents as soft tissue swelling (oedema) especially around the eyes, the lips and the hands but this is rarely itchy. This can be very alarming to the patient. It can also be dangerous if mucosal areas such as the mouth and larynx are involved but fortunately this is very rare.

Physical urticarias

Occasionally, urticaria can be caused by physical stimuli such as cold (cold urticaria), deep pressure (delayed pressure urticaria), stress or heat (cholinergic urticaria), sunlight (solar urticaria – p. 1215), water (aquagenic urticaria) or chemicals such as latex (contact urticaria).

Cholinergic urticaria is one of the commonest physical urticarias and has rather different clinical lesions from the other forms. Small itchy papules rather than wheals appear on the upper trunk and arms after exercise or anxiety.

Pressure can cause two types of urticaria. More superficial pressure can cause **dermographism** which is relatively common. This presents as urticated wheals occurring a few minutes after application of light pressure. Even scratching or rubbing will bring up linear wheals in dermographic individuals. **Delayed pressure urticaria** is rare and occurs as deep swellings some hours after pressure is removed (e.g. on the soles of the feet or under a tight belt).

Investigations

The history is the most useful factor in diagnosing urticaria. Routine investigation is probably not justified unless the history suggests one of the underlying causes listed above. The physical urticarias should be reproducible by applying the relevant stimulus.

Treatment

Any identifiable underlying cause should be treated appropriately. Patients should avoid salicylates and opiates as they can degranulate mast cells. Oral antihistamines (H₁ blockers) are the most useful in treating the idiopathic cases. Therapy should be started with regular use of a non-sedating antihistamine (e.g. cetirizine 10 mg daily or loratadine 10 mg daily). If control proves difficult, addition of a sedating antihistamine, an H₂ blocker or dapsone may be helpful. Angio-oedema of the mouth and throat may require urgent treatment with intramuscular adrenaline (epinephrine) and intravenous steroids (see Emergency Box 3.1).

Figure 24.18 Urticaria.

Prognosis

Most cases of 'idiopathic' urticaria last a few weeks to months before disappearing spontaneously. The majority of these will be controlled with an antihistamine. A small percentage of people go on to develop chronic urticaria which can last for several months or years. The physical urticarias (especially cholinergic urticaria) are more persistent, often lasting for years, and they are often resistant to therapy.

Urticarial vasculitis

This is a variant of urticaria and should be suspected if individual urticarial lesions last longer than 24 hours and leave bruising behind after resolution. There is often an associated arthralgia or myalgia, and a small proportion may go on to develop an autoimmune rheumatic disease. The diagnosis is confirmed by skin biopsy. A full vasculitis screen should be carried out for an underlying cause (p. 537).

Treatment is with antihistamines, oral dapsone (50–100 mg daily) or immunosuppressants.

Hereditary angio-oedema

This is a rare autosomal dominant condition due to an inherited deficiency of C1 esterase inhibitor (C1-INH) which causes massive activation of the complement system, increased bradykinin levels and thus angio-oedema. The defect may be due to either reduced function (type I – 85%) or reduced levels (type II – 15%) and both these are due to mutations in the Serping-1 gene. A low serum C4 level is a good screening test (Table 24.5). Rarely this condition is acquired (due to autoantibody production against C1-INH) and associated with lymphoma or SLE and it presents at a later age. These types show low C1-INH but also low C1q levels.

A very rare X-linked dominant form exists in which C1-INH levels and function are normal (type III) and this is due to factor XII gene mutation. This type is much more common in females and is made worse by high oestrogen levels such as in pregnancy.

Clinical features

Hereditary angio-oedema presents with attacks of non-itchy cutaneous angio-oedema (but no urticaria), which may last up to 72 hours. It may also present with recurrent abdominal pain (due to intestinal oedema) and there may be a family

history of sudden death (due to laryngeal involvement). It presents before the age of 15 in 75% of cases. A nonspecific erythematous rash (or erythema marginatum) may precede an attack of angio-oedema but urticaria itself is not a feature.

Treatment

In the acute setting treatment is with C1 esterase inhibitor concentrates and fresh frozen plasma. Adrenaline (epinephrine) and steroids are often ineffective. Two new therapies, icatibant (a bradykinin B2 receptor antagonist) and ecallantide (a plasma kallikrein inhibitor), are both being used for severe acute attacks.

Maintenance treatment with the anabolic steroid stanozolol (or danazol) stimulates an increase in hepatic synthesis of C1 esterase inhibitor but this should not be used in children. Family members should be screened.

Pityriasis rosea

Pityriasis rosea is a self-limiting rash seen in adolescents and young adults. The cause is unknown but it is thought to be a viral or post-viral rash. There is an increased incidence in spring and autumn and outbreaks may occur in institutions.

Clinical features

The rash consists of circular or oval pink macules with a collarette of scale and is more prominent on the trunk than the limbs. The long axis of the oval lesions tends to run along dermatomal lines giving a 'Christmas tree' pattern on the back. The rash may be preceded by a large solitary patch with peripheral scaling ('herald patch') and this is most commonly found on the trunk. The rash is usually asymptomatic and spontaneously resolves over 4–8 weeks.

Treatment

Treatment is not normally required but a weak steroid cream may help relieve any itch. In persistent cases UVB (p. 1215) may be helpful.

Lichen planus

Lichen planus is a pruritic inflammatory dermatosis that is commonly associated with mucosal involvement and rarely with nail dystrophy and scarring alopecia.

The cause is unknown but is possibly a T-cell-driven immune mechanism as an almost identical rash can be caused by certain drugs (e.g. beta-blockers, gold, levamisole, ACE inhibitors or antimalarials) or by graft-versus-host disease and in chronic HBV, HCV liver disease.

Pathology

Hyperkeratosis with thickening of the granular cell layer is seen in the epidermis. A dense T cell infiltrate is seen at the dermoepidermal junction, which becomes ragged and saw-toothed. The basal layer shows liquefactive degeneration with colloid (apoptotic) bodies in the upper dermis.

Clinical features

The rash is characterized by small, purple flat-topped, polygonal papules that are intensely pruritic (Fig. 24.19). It is common on the flexors of the wrists and the lower legs but can occur anywhere. There may be a fine lacy white pattern on the surface of lesions (Wickham's striae). Lesions can fuse into plaques, especially on the lower legs and in black Africans. Hyperpigmentation is common after resolution of lesions, especially in people with pigmented skin. Atrophic, hypertrophic and annular variants can occur. Lichen planus

lesions often localize to scratch marks. If lesions occur in the scalp they may cause a scarring alopecia.

Mucosal involvement is common. The mouth is the most commonly affected but the anogenital region can be involved. It can present as lacy white streaks, white plaques or as ulceration. The prominent mucosal symptom is of severe pain rather than itch. Nails may be dystrophic and can be lost altogether (with scarring and 'wing' formation) in severe disease.

Prognosis

The condition often clears by 18 months but can recur at intervals. The hypertrophic and atrophic variants and mucosal disease are more persistent, lasting for years. Ulcerative mucosal disease is pre-malignant.

Treatment

This requires the use of potent topical steroids (0.05% clobetasol propionate) and occasionally oral prednisolone (30 mg daily for 2–4 weeks). Occlusion of topical treatments can be helpful. Oral lesions also require high potency steroids given as an ointment, gel or mouth wash. Resistant cases may respond to PUVA, oral retinoids (0.5 mg/kg per day) or azathioprine (1–2 mg/kg daily). Topical 0.1% tacrolimus ointment or pimecrolimus has proved a very useful therapy for painful oral disease unresponsive to steroids.

Granuloma annulare

Granuloma annulare is a dermatosis predominantly of children and young adults. It is characterized by clusters of small dermal papules (with no surface change) that often form into rings or part of a ring. They are common on the dorsal surface of the hands and feet. They are flesh coloured or slightly erythematous and are usually asymptomatic. As they heal, the centre becomes dusky and altered in texture. A deep form, which is tender, exists in children. Diffuse granuloma annulare may be associated with diabetes mellitus. The pathology shows a granulomatous dermal infiltrate with foci of degeneration of collagen (necrobiosis). Spontaneous resolution often occurs after months to years but cryotherapy or triamcinolone injection may help localized disease.

Lichen sclerosis

Lichen sclerosis is a common inflammatory dermatosis that occurs in all age groups and particularly affects the anogenital region. It is more common in post-menopausal females. The underlying cause is unknown but HLA associations and

studies showing antibodies to extracellular matrix protein-1 suggest an autoimmune aetiology. It presents with atrophic ivory-white patches with a well-defined edge on the vulva, glans penis, foreskin or perianal skin. Telangiectasia may be seen over the surface. Occasionally lesions involve the shaft of the penis and the urethral meatus. Lesions are often itchy but may be sore at times. Longstanding vulval lesions may be associated with fissuring and a marked loss of architecture, especially of the clitoral hood and the labia minora, which may become fused. Early lesions in young girls may present as haemorrhagic blisters and these are occasionally mistaken as signs of sexual abuse. Involvement of the foreskin can cause phimosis and dyspareunia, and urethral disease may interfere with micturition. Perianal lesions may fissure and cause constipation.

Rarely lichen sclerosis can affect non-genital skin. This is most common in females and clinically it may show rather more hyperkeratosis and follicular plugging than is seen in the anogenital region.

Diagnosis

Diagnosis is usually clinical without the need for biopsy.

Treatment

Treatment with very potent topical steroids helps control the symptoms. Hydroxychloroquine (200 mg twice daily) is used in resistant cases. The condition may burn itself out after many years, especially in children. There is a risk of developing squamous cell carcinoma in longstanding lesions. Male patients may require circumcision if phimosis does not respond to medical therapy.

FACIAL RASHES

Facial rashes often cause diagnostic confusion but a close examination of the clinical signs should help differentiate the underlying cause (Table 24.6). All facial rashes, by virtue of their visibility, can cause significant distress to the patient.

Acne vulgaris

Acne is a very common facial rash occurring in over 85% of adolescents and frequently continuing into early and mid-adult life. Occasionally it can cause profound psychological disturbance and depression, even suicide. The cause is multifactorial but follicular epidermal hyperproliferation, blockage of pilosebaceous units with surrounding inflammation, increased sebum production are critical factors in the pathological process (Fig. 24.20a) as is infection with *Propionibacterium acnes*.

Propionibacterium acnes induced inflammation has recently been shown to occur via activation of Toll-like

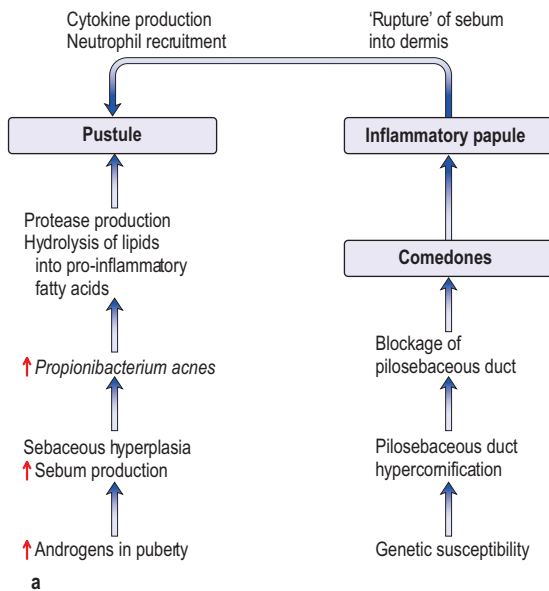

Figure 24.20 Acne vulgaris. (a) Pathophysiology. (b) Skin lesion.

receptor 2, which leads to production of pro-inflammatory cytokines, e.g. IL-8, IL-12 and TNF- α .

Clinical features

Acne presents in areas rich in sebaceous glands such as the face, back and sternal area. The three cardinal features are:

1. Open comedones (blackheads) or closed comedones (whiteheads)
2. Inflammatory papules
3. Pustules (Fig. 24.20b).

The skin may be very greasy (seborrhoea). Rupture of the inflamed lesions may lead to deep-seated dermal inflammation and nodulocystic lesions, which are more likely to cause facial scarring. A premenstrual exacerbation of acne is sometimes noticed. There is a tendency for spontaneous improvement over a number of years but acne can persist unabated into adult life.

A number of clinical variants exist:

- **Infantile acne.** Facial acne is occasionally seen in infants and is sometimes cystic. It is thought to be due to the influence of maternal androgens and resolves spontaneously.
- **Steroid acne.** Acne may occur secondary to corticosteroid therapy or Cushing's syndrome. Clinically the rash often appears as a pustular folliculitis on the trunk without comedones.

- **Oil acne.** This is an industrial disease seen in workers who have prolonged contact with oils or other hydrocarbons and is common on the legs and other exposed sites.
- **Acne fulminans.** This is a rare variant seen most commonly in young male adolescents. Severe necrotic and crusted acne lesions appear associated with malaise, pyrexia, arthralgia and bone pain (due to sterile bone cysts). It requires urgent treatment with oral prednisolone (30–40 mg daily) and analgesics followed by a course of oral isotretinoin (see below).
- **'Acne conglobata'.** Cystic acne with abscesses and interconnecting sinuses.
- **'Acne excoriée'.** Deeply excoriated and picked acne with associated scarring. It is much more common in females.
- **'Follicular occlusion triad'.** This is a rare disorder most commonly seen in black Africans. It is characterized by the presence of severe nodulocystic acne, dissecting cellulitis of the scalp (p. 1233) and hidradenitis suppurativa (p. 1198). This may be caused by a problem of follicular occlusion.

Treatment

This is aimed at decreasing sebum production, decreasing bacteria, normalizing duct keratinization and decreasing inflammation.

Regular washing with acne soaps to remove excess grease is helpful (normal soaps can be comedogenic). 'Picking' should be discouraged.

First-line therapy

Mild acne can respond to a variety of topical agents, e.g. keratolytics (benzoyl peroxide, azelaic acid) or topical retinoids (tretinoin or isotretinoin) or retinoid-like agents (adapalene). Topical antibiotics, e.g. erythromycin or clindamycin, are used for inflammatory acne. All topical agents can cause problems with irritation.

Second-line therapy

- **Low-dose oral antibiotic therapy** often helps but must be given for at least 3–4 months. Oxytetracycline 500 mg twice daily is often used first. Minocycline 100 mg daily, erythromycin 500 mg twice daily or trimethoprim 100 mg twice daily are also used.
- An extra treatment, cyproterone acetate 2 mg/ethinylestradiol 35 μ g (co-cyprindol), is of value in females if there is no contraindication to oral contraception. This acts as a normal combined contraceptive but has antiandrogen activity. It may take 6–8 months to have its maximum effect. There is an increased incidence of DVT.

Third-line therapy

Third-line treatment with an oral retinoid drug (isotretinoin) should be given if:

- the above measures fail
- there is nodulocystic acne with scarring
- there is severe psychological disturbance.

Use of retinoids (isotretinoin or acitretin). Retinoids are synthetic vitamin A analogues that affect cell growth and differentiation. They are very teratogenic. Isotretinoin is a 'hospital-only drug' in most countries due to its teratogenicity and is restricted to the use of dermatologists and a few trained family doctors. A pregnancy test, contraceptive

advice and signed consent are mandatory prior to its use in fertile women, and pregnancy testing must be repeated monthly during therapy. It is given as a 4-month course at a dose of 0.5–1 mg/kg per day. Over 90% of individuals will respond to this therapy and 65% of people will obtain a long-term 'cure'.

Patients must avoid pregnancy during therapy and for 1 month after stopping isotretinoin (but for 2 years after stopping acitretin (used only in psoriasis) as it is very lipophilic). Both drugs cause drying of the skin, especially of the lips and nasal mucosa. Hair thinning and exercise-induced myalgia are not uncommon. Blood count, liver biochemistry and fasting lipids need to be monitored during therapy. In a few individuals retinoids may cause depression but it should also be remembered that acne itself has been a cause of suicide.

A number of physical techniques are currently under assessment (e.g. lasers, blue light, microdermabrasion) but they are not as effective as isotretinoin and can be very expensive as repeat treatments are often needed.

Rosacea

Rosacea (Fig. 24.21) is a common inflammatory rash predominantly affecting the face. The onset is usually in middle age and it is commoner in women. It often causes significant psychological distress.

The cause is unknown. Theories have suggested an underlying problem in vasomotor stability of blood vessels or a possible role of the skin mite *Demodex*.

Clinical features

The cardinal features are of facial flushing and inflammatory papules and pustules affecting the nose, forehead and cheeks. The flushing may precede the other signs by some years. There are no comedones. Additional features include dilated blood vessels (telangiectasia), inflammation of the eyelid margins (blepharitis), keratitis and sebaceous gland hypertrophy, especially of the nose. The latter is commoner in men and can cause a disfiguring enlargement of the nose called rhinophyma. The flushing may be exacerbated by alcohol, hot drinks, sunlight and changes in ambient temperature. Prolonged use of topical steroids can exacerbate or trigger the condition. As the disease progresses the flushing may be replaced by a permanent erythema.

Treatment

This is suppressive rather than curative. Long-term use of topical 0.075% metronidazole or topical 15% azelaic acid

may help. Avoid topical steroids. A 3-month course of oral tetracycline (500 mg twice daily) is also helpful. Oral metronidazole (400 mg twice daily) or oral isotretinoin (0.5 mg/kg per day) is occasionally given in resistant cases (p. 1213). The papules and pustules tend to respond best to therapy but repeat courses may be necessary. The flushing and erythema are often resistant to treatment but cosmetic camouflage can be helpful for these features. Intense pulse light or pulsed dye laser therapy can help the erythema and telangiectasia but often needs to be repeated as rosacea tends to recur. Rhinophyma can be treated with plastic surgery or by carbon dioxide laser.

Perioral dermatitis

Perioral dermatitis is a common rash found around the mouth, especially in young females. The exact cause is unknown but it often has an iatrogenic component as topical steroids often exacerbate the condition in the long term.

Clinical features

It presents with erythema, scaling, papules and occasionally pustules around the mouth. It usually spares a halo of skin immediately adjacent to the lips. Rarely there is involvement around the eyes.

Treatment

Treatment involves stopping topical steroids although they may have to be withdrawn slowly to prevent too severe a rebound after withdrawal. The mainstay of treatment is with a 3–4-month course of low-dose oxytetracycline or erythromycin (both 500 mg twice daily) and topical metronidazole.

Blushing

Facial flushing in response to emotional stimuli is a normal physiological response that can be debilitating if it becomes sufficiently frequent to interfere with work and social interaction. Causes may be both psychological and physiological. Non-emotional causes should be excluded, e.g. postmenopause, drugs, and carcinoid syndrome.

Treatment includes cognitive behavioural therapy, cosmetic camouflage, beta-blockers and clonidine. Selective serotonin reuptake inhibitors may help associated depression and anxiety. Botulinum toxin and surgical sympathectomy, advocated by some, are not universally accepted treatments.

PHOTODERMATOLOGY

Sunlight. Light in the ultraviolet (UV) part of the spectrum combines short, medium and long wavelengths (UVC, UVB and UVA, respectively). Both UVB and UVA can penetrate the atmosphere and reach the skin. This light energy is potentially mutagenic and carcinogenic but it can also suppress cutaneous inflammation.

Photosensitive rashes usually appear on sites exposed to the sun's rays, such as the face, the anterior 'V' of the chest, the ears and the backs of the hands. Certain 'protected' areas are characteristically spared such as under the chin or the upper eyelid and between the finger webs. Porphyria, drug sensitivity and lupus erythematosus should be excluded in all photosensitive patients.

Photosensitive rashes may be divided into photoexacerbated/provoked rashes and the idiopathic photodermatoses (Table 24.7). The former are discussed on pages 535 (SLE), 210 (pellagra) and 1043 (porphyria).

Figure 24.21 Rosacea. Papules and pustules on a background erythema. There are no comedones.

Table 24.7 Differential diagnosis of photosensitive rashes

Photoexacerbated/provoked rashes	
Systemic disease	SLE (p. 1219), CDLE (p. 535), SCLE (p. 1218)
Metabolic disease	Porphyrias (pp. 1043), pellagra (p. 210)
Drugs	Thiazides, phenothiazines, tetracyclines, amiodarone
Plant phototoxins	Phytophotodermatitis (photosensitivity induced by contact of the skin with certain plants, e.g. celery, hogweed, rue, lime, fig tree)
Skin disease	Rosacea Rarely atopic eczema, psoriasis, lichen planus (these normally improve in sunlight)
Idiopathic photodermatoses	
Polymorphic light eruption Chronic actinic dermatitis Solar urticaria	
CDLE, chronic discoid lupus erythematosus; SCLE, subacute cutaneous lupus erythematosus; SLE, systemic lupus erythematosus.	

Phototherapy and photoprotection

Phototherapy

UVB and UVA both have a suppressive effect on cutaneous inflammation and there is increasing evidence that they can suppress systemic immunoreactivity to some degree. However, both types can cause skin ageing and predispose to skin malignancy if excessive doses are used. This is more of a problem in white-skinned individuals. Unaffected regions of skin or high-risk areas like the scrotum can be screened during phototherapy. UVB is less carcinogenic than UVA.

Narrow-band UVB (311 nm) is used therapeutically in the treatment of eczema and psoriasis (especially in children) and is usually given three times per week for 6–10 weeks. Eye protection needs to be worn during therapy.

Narrow-band UVB is usually used in preference to PUVA. UVA is relatively ineffective on its own so is used in conjunction with a photosensitizer ('psoralen'), hence the term 'PUVA'. PUVA is given twice a week and eye protection must be worn for the whole of the treatment day as the psoralen sensitizes the retina. Its use is limited by its carcinogenic potential (especially induction of squamous cell carcinoma of the skin). A maximum dose is given over a lifetime (1000 joules or 200 sessions approximately).

Sunbeds are used for tanning and consist of predominantly UVA light and are therefore rarely effective in treating skin disease. If used frequently there is an increased risk of skin cancer and premature ageing.

Photoprotection

There are two broad classes of sunblock cream: they either absorb UV light (e.g. aminobenzoic acid or methoxycinnamate) or reflect it (e.g. titanium dioxide). Most modern creams protect against UVA and UVB to varying degrees. UVB protection is graded by the 'sun protection factor' (SPF): an SPF of 15 implies you can spend 15 times longer in the sun before burning providing it is applied correctly. SPFs above 15 confer little extra protection. There is no standardized way of assessing efficiency against UVA. Some sunscreens (especially aminobenzoates) may rarely cause photosensitization. This can be proven by photopatch testing.

Idiopathic photodermatoses

Polymorphic light eruption (PLE)

This is the most common photosensitive eruption in temperate regions, affecting up to 10–20% of the population. It is most common in young women. In many it is mild and often goes undiagnosed. An itchy rash appears some hours after sun exposure which is strictly confined to the exposed sites. Lesions may be papules, vesicles or plaques. They can last for several hours or several days. The condition starts in spring and often improves during the summer because of skin 'hardening'.

Treatment

Avoidance of sunlight and the use of sunblocks are helpful in mild cases. Topical steroids help treat an attack. In those individuals who only get PLE after very intense sun exposure (e.g. on sunny holidays) a short course of oral prednisolone (30 mg daily for 7–10 days) will often prevent or treat an attack. For resistant cases 'desensitization' with low-dose PUVA (or narrow-band UVB) in the springtime may be required but patients will need to 'top up' their sun exposure from natural sunlight during the summer to keep their skin desensitized.

Chronic actinic dermatitis (photosensitive eczema, actinic reticuloid)

This is a relatively rare type of eczema occurring in a photosensitive distribution over the face, neck and hands. It typically affects middle-aged or elderly males. There may be a pre-existing eczema so the subsequent development of photosensitivity is often missed. This is further confounded by the fact that the eczema usually will spread to affect skin not exposed to sunlight, and the patient can become erythrodermic. The skin has typical features of eczema but there is often marked skin thickening. Histology is often atypical and can look almost lymphoma-like. The diagnosis can be confirmed by specialist monochromator light-testing. The most severe cases can be exacerbated by even artificial lighting as these patients can become exquisitely photosensitive.

Treatment

This consists of strict avoidance of sunlight including high-factor sunblocks and screening of house and car windows. Topical steroids and emollients are useful in milder cases. Oral prednisolone may be needed and azathioprine (1–2 mg/kg daily) is used for long-term suppression. Low-dose phototherapy under steroid cover may help with 'desensitization'.

Solar urticaria

This is extremely rare. Itchy urticarial lesions occur within minutes of sun exposure and characteristically settle within 1–2 hours. Sun avoidance, sunblocks, H₁ antihistamines and low-dose phototherapy are all used in treatment.

ERYTHRODERMA

Erythroderma, meaning 'red skin', refers to the clinical state of inflammation or redness of all (or nearly all) of the skin. It is sometimes called exfoliative dermatitis, but dermatitis is not always present.

Photodermatology

Erythroderma

HIV infection
Toxic shock syndrome

Aetiology

There are a number of underlying causes (Table 24.8); previous skin disease and drugs are the most common.

Clinical features

It is commoner in males and later in life. Patients often complain of their skin feeling 'tight' as well as itchy. Longstanding erythroderma is often associated with hair loss, ectropion of the eyelids and even nail shedding. Systemic symptoms are common such as malaise, pyrexia, widespread lymphadenopathy and other complications (see below). Erythroderma can occasionally lead to death so it should be regarded as a medical 'emergency'.

Examination should specifically look for pustules and nail changes suggestive of psoriasis.

A skin biopsy may further help to elucidate the cause, especially of cutaneous lymphoma. T cell receptor gene rearrangement studies (looking for evidence of clonal T cell expansion in the skin and blood) are also useful in the diagnosis of lymphoma. Lymph node biopsy is also useful in lymphoma. In non-malignant disease lymph nodes normally show nonspecific, reactive (dermatopathic) changes. A number of cases defy an exact diagnosis.

Complications

The skin is one of the largest organs of the body, so perhaps it is no surprise that inflammation of the whole organ can cause metabolic and haemodynamic problems. Examples are:

- High-output cardiac failure from increased blood flow
- Hypothermia from heat loss
- Fluid loss by transpiration
- Hypoalbuminaemia
- Increased basal metabolic rate
- 'Capillary leak syndrome'.

Capillary leak syndrome is the most severe complication and has been responsible for a fatal outcome in some cases of psoriasis, although this is extremely rare. It is thought that the inflamed skin releases large quantities of cytokines that cause a generalized vascular leakage. This can cause cutaneous oedema and acute lung injury (p. 883).

Treatment

Treatment of erythroderma is best initiated in hospital. Patients must be kept very warm (with space blankets and heaters). Their vital signs should be monitored regularly, particularly fluid balance. Changes in serum electrolytes and

albumin, as well as circulatory status, should be corrected. Swabs should be taken to detect any secondary skin infection.

The skin condition is treated with bed rest and either a bland emollient or a mild topical steroid. All non-essential drugs should be stopped. Where known, the underlying cause should be treated. The blanket use of systemic steroid therapy for erythroderma remains controversial in view of possible side-effects.

Capillary leak syndrome will often require specialized haemodynamic management in an intensive care unit.

CUTANEOUS SIGNS OF SYSTEMIC DISEASE

Some dermatoses are associated with a variety of underlying systemic diseases. Furthermore, some medical conditions may present with cutaneous features.

Erythema nodosum

Erythema nodosum has a number of underlying causes (Table 24.9). It presents as painful or tender dusky blue-red nodules, commonly over the shins or lower limbs, which fade over 2–3 weeks leaving a bruised appearance (see Fig. 24.39). It is most common in young adults, especially females. It may be associated with arthralgia, malaise and fever. Inflammation occurs in the dermis and the subcutaneous layer (panniculitis).

Treatment is of the symptoms with non-steroidal anti-inflammatory drugs (avoid in pregnancy), light compression bandaging and bed rest, as the condition resolves spontaneously. The underlying cause should be treated. In very persistent cases dapsone (100 mg daily), colchicine (500 µg twice daily) or prednisolone (up to 30 mg daily) can be useful.

Erythema multiforme

Erythema multiforme (EM) is a hypersensitivity rash of acute onset frequently caused by infection or drugs. A cell-mediated cutaneous lymphocytotoxic response is present.

In 50% of cases, the cause is not found but the following should be considered:

- Herpes simplex virus (the most common identifiable cause)
- Other viral infections (e.g. Epstein-Barr virus (EBV), orf)
- Drugs (e.g. sulphonamide, anticonvulsants)
- Mycoplasma infection
- Autoimmune rheumatic disease (e.g. SLE, polyarteritis nodosa)
- HIV infection

Table 24.10 Clinical spectra of erythema multiforme, Stevens–Johnson syndrome and toxic epidermal necrolysis

Diagnosis	Skin lesions	Mucosal lesions	Other signs/symptoms
Erythema multiforme (EM)	Three-ring target lesions, often hands and feet	EM major only	Recent infection (herpes simplex, mycoplasma)
Stevens–Johnson syndrome (SJS)	Scattered macules/blisters scattered over face, trunk proximal limbs (<10% body surface area) Recent drug exposure Occasional two-ring target lesion	Always	Fever Skin tenderness
Toxic epidermal necrolysis (TEN)	As for SJS but >30% body surface area involved	Always	As for SJS Respiratory and gastrointestinal lesions Hypotension Decreased consciousness
SJS/TEN overlap	As for SJS (10–30% body surface area involved)	Always	

Figure 24.22 Erythema multiforme major. (a) Target lesions of the palm. (b) Mucosal involvement around the mouth.

- Wegener's granulomatosis
- Carcinoma, lymphoma.

Clinically the lesions can be erythematous, polycyclic, annular or show concentric rings ('target lesions') (Fig. 24.22). Frank blistering is not uncommon. The rash tends to be symmetrical and commonly affects the limbs, especially the hands and feet where palms and soles may be involved. Occasionally, there is severe mucosal involvement leading to necrotic ulcers of the mouth and genitalia, and a conjunctivitis ('EM major' – not to be confused with Stevens–Johnson syndrome – see Table 24.10).

The term 'EM minor' is used for cases without mucosal involvement.

Erythema multiforme usually resolves in 2–4 weeks. Rarely, recurrent erythema multiforme can occur and this is triggered by herpes simplex infection in 80% of cases.

Treatment

This is symptomatic and involves treating the underlying cause. Some advocate the use of oral steroids in severe mucosal disease but this remains controversial.

Recurrent erythema multiforme can be treated with prophylactic oral aciclovir (200 mg twice daily) even if no cause has been found, as 80% of cases appear to be driven by herpes simplex virus. In resistant cases, azathioprine (1–2 mg/kg daily) is used.

Pyoderma gangrenosum

Pyoderma gangrenosum is a condition of unknown aetiology that presents with erythematous nodules or pustules which

Figure 24.23 Pyoderma gangrenosum.

frequently ulcerate (Fig. 24.23). The ulcers can be large and grow at an alarming speed. The ulcer has a typical bluish black ('gangrenous') undermined edge and a purulent surface ('pyoderma'). There may be an associated pyrexia and malaise. Biopsy through the ulcer edge shows an intense neutrophilic infiltrate and occasionally a vasculitis but the diagnosis depends mostly on the clinical appearance. The main causes are:

- Inflammatory bowel disease
- Rheumatoid arthritis
- Myeloma, monoclonal gammopathy, leukaemia, lymphoma
- Liver disease (e.g. primary biliary cirrhosis)
- Idiopathic (>20% in some series).

Treatment

This is with very potent topical steroids or 0.1% tacrolimus ointment. High-dose oral steroids may be needed to prevent rapidly progressive ulceration. Oral dapsone and minocycline are also used. Other immunosuppressants, such as ciclosporin, are useful in resistant cases. The underlying cause should be treated.

Acanthosis nigricans

Acanthosis nigricans presents as thickened, hyperpigmented skin predominantly of the flexures (Fig. 24.24). It can appear warty or velvety when advanced. In early life it is seen in obese individuals who have very high levels of insulin owing to insulin resistance (and this is sometimes termed 'pseudo-acanthosis nigricans'). In older people it normally reflects an underlying malignancy (especially gastrointestinal tumours). Rarely it is associated with hyperandrogenism in females.

Acanthosis nigricans in an obese individual.

Figure 24.24 Acanthosis nigricans.

Morphea – hyperpigmentation and scarring on the trunk.

Treatment

Topical or oral retinoids (0.5 mg/kg per day) may help (p. 1213), and weight loss is advised in the obese. Any underlying malignancy should be treated.

Dermatomyositis (see also p. 540)

The rash is distinctive and often photosensitive. Facial erythema and a magenta-coloured rash around the eyes with associated oedema are usually present. Bluish red nodules or plaques may be present over the knuckles (Gotttron's papules) and extensor surfaces. The nail folds are frequently ragged with dilated capillaries. The diagnosis is made from the clinical appearance, muscle biopsy, electromyography (EMG) and a serum creatine phosphokinase. Skin biopsy is not diagnostic.

There is a childhood form, which usually occurs before the age of 10 and which eventually resolves. This type is associated with calcinosis in the skin, weak muscles and contractures. Life-threatening bowel infarction can also occur in the childhood form. The adult form usually occurs after the age of 40. Some cases are associated with an underlying malignancy whereas some are associated with other autoimmune rheumatic diseases. This latter group may overlap with scleroderma and lupus erythematosus.

Treatment

Skin disease may respond to sunscreens and hydroxychloroquine (200 mg twice daily) as well as immunosuppressants, e.g. prednisolone, azathioprine or ciclosporin.

Scleroderma

The term scleroderma (see also p. 538) refers to a thickening or hardening of the skin owing to abnormal dermal collagen. It is not a diagnostic entity in itself. Systemic sclerosis and morphea both show sclerodermatous changes but are separate conditions.

Systemic sclerosis (often called scleroderma) has cutaneous and systemic features and is discussed fully on page 538.

Morphea is confined to the skin and usually presents in children or young adults. It is commoner in females and the cause is unknown. Lesions are usually on the trunk and appear as bluish red plaques which progress to induration

Figure 24.25 Chronic discoid lupus erythematosus, showing scaling, atrophy and hypopigmentation.

and then central white atrophy. A linear variant exists in childhood which is more severe as it can cause atrophy of underlying deep tissues and thus cause unequal limb growth or scarring alopecia.

Rarely sclerodermatous skin changes may be seen in Lyme disease (acrodermatitis chronica atrophicans), chronic graft-versus-host disease, polyvinyl chloride disease, eosinophilic myalgia syndrome (due to tryptophan therapy) and bleomycin therapy.

Lupus erythematosus (LE)

There are three clinical variants to this disease but some patients may show features of more than one type.

- Chronic discoid lupus erythematosus (CDLE)
- Subacute cutaneous lupus erythematosus (SCLE)
- Systemic lupus erythematosus (SLE).

The aetiology is unknown but variable autoantibodies may be found in all types, suggesting that it is an autoimmune disorder. Very rarely it can be induced by certain drugs such as phenothiazines, hydralazine, methyl dopa, isoniazid, tetracycline, mesalazine and penicillin.

Chronic discoid lupus erythematosus (CDLE)

CDLE is the most common type of LE seen by dermatologists and more frequently affects females. Clinically it presents with fixed erythematous, scaly, atrophic plaques with telangiectasia, especially on the face or other sun-exposed sites (Fig. 24.25). Hypopigmentation is common and follicular plugging may be apparent. Scalp involvement may lead to a scarring alopecia. Oral involvement (erythematous patches or ulceration) occurs in 25% of cases.

CDLE may be triggered and exacerbated by UV exposure. A few patients may also suffer with Raynaud's phenomenon or unusual chilblain-like lesions (chilblain lupus). Only 5% of cases will go on to develop SLE but this is more common in children. Serum anti-nuclear factor (ANF) is positive in 30% of cases.

Skin biopsy shows a dense patchy, dermal cellular infiltrate (mostly T cells) which often is centred on appendages. Epidermal basal layer damage, follicular plugging and hyperkeratosis may be present. Direct immunofluorescence studies of lesional skin may show the presence of IgM and C3 in a granular band at the dermoepidermal junction ('lupus band').

Treatment

First-line therapy is with sunscreens and potent topical steroids. Certain oral antimalarials (hydroxychloroquine 100–200 mg twice daily and mepacrine 100 mg daily) can prove very useful and are generally safe for long-term intermittent use. Oral prednisolone is beneficial but its use is limited by its side-effect profile. Azathioprine, retinoids, ciclosporin and thalidomide can be useful in resistant cases.

Prognosis

The disease is usually chronic although it often fluctuates in severity. CDLE remains confined to the skin in most patients and it will eventually go into remission in up to 50% of cases (after many years).

Subacute lupus erythematosus (SCLE)

SCLE is a rare cutaneous variant of LE. It presents with widespread indurated, sometimes urticated erythematous lesions, often on the upper trunk. The lesions can also be annular. Photosensitivity is often a prominent feature. Complications, such as arthralgia and mouth ulceration, are seen but significant organ involvement is rare. ANF and extractable nuclear antibodies (anti-Ro and anti-La) are usually positive (see p. 537).

Treatment is with oral dapsone, antimalarials or systemic immunosuppression (prednisolone and ciclosporin).

Systemic lupus erythematosus (SLE)

(see also p. 535)

The cutaneous involvement of SLE is one of the minor problems of the disease but it may be the presenting feature.

Features include macular erythema over the cheeks, nose and forehead ('butterfly rash' – Fig. 24.26). Palmar erythema, dilated nail-fold capillaries, splinter haemorrhages and digital infarcts of the finger tips may also be seen but are not always noticed by the patient. Joint swellings, livedo reticularis and purpura are occasionally seen. Rarely SLE can be complicated by an atypical erythema multiforme-like rash ('Rowell's syndrome').

Treatment (p. 537) is usually managed by a rheumatologist.

Pruritus

The pathophysiology of pruritus (itch) is poorly understood but may be due to peripheral mechanisms (as in skin disease),

central or neuropathic mechanisms (as in multiple sclerosis), neurogenic (as in cholestasis/ μ -opioid receptor stimulation) or psychogenic mechanisms (e.g. parasitophobia). Evidence suggests that low stimulation of unmyelinated C-fibres in the skin is associated with the sensation of itch (high stimulation produces pain). Histamine, tachykinins (e.g. substance P) and cytokines (e.g. interleukin-2) may also play a role peripherally in the skin. The major nerve pathways for itch and the influence of the central nervous system are not well characterized but opioid μ -receptor-dependent processes can regulate the perception and intensity of itch.

Pruritus (see p. 1207, lichen simplex, nodular prurigo/neurodermatitis) in the absence of a demonstrable rash can be caused by a number of different medical problems (Table 24.11).

Asteatotic eczema and cholinergic urticaria are common causes of pruritus where the rash is often missed. The term idiopathic pruritus or 'senile' pruritus probably overlaps with asteatotic eczema and this is common in the elderly.

Treatment involves avoiding soaps and symptomatic measures (as for asteatotic eczema). Phototherapy, low-dose amitriptyline or gabapentin may help intractable cases. Underlying medical problems should be treated.

Sarcoidosis

Sarcoidosis (see also p. 845) is a multisystem granulomatous disorder of unknown aetiology. It may present as reddish brown dermal papules and nodules, especially around the eyelid margins and the rim of the nostrils. More polymorphic lesions (papules, nodules and plaques) may appear on the body. It is most common in black Africans where it is often accompanied by hypo- or hyperpigmentation. Rarely it presents with a bluish red infiltration or swelling, especially of the nose or ears, called *lupus pernio*. Both these types of lesion are to be seen anywhere on the body but are common on the face. Erythema nodosum (p. 1216) of the shins is sometimes seen in acute-onset sarcoidosis. Erythema nodosum is an immunological reaction and not due to sarcoid tissue infiltration. Swollen fingers from a dactylitis may also be present. Whilst sarcoidosis may be confined to the skin, all patients should be investigated for evidence of systemic disease (p. 847).

Treatment of cutaneous lesions includes very potent topical steroids (0.05% clobetasol propionate), intralesional steroids, oral steroids and occasionally methotrexate or antimalarials.

Neurofibromatosis type 1 (von Recklinghausen's disease)

Type 1 neurofibromatosis is an autosomal dominant condition with high levels of penetrance. It often presents in childhood with a variety of cutaneous features. Many cases are new mutations in the *NF1* gene. Early signs include

Figure 24.26 Systemic lupus erythematosus – macular erythema on the cheeks ('butterfly rash').

Table 24.11 Medical conditions associated with pruritus

Iron deficiency anaemia
Internal malignancy (especially lymphoma)
Diabetes mellitus
Chronic kidney disease
Chronic liver disease (especially primary biliary cirrhosis)
Thyroid disease
HIV infection
Polycythaemia vera

café-au-lait spots (brown macules, >2.5 cm in diameter and more than five lesions) and axillary freckling. Lisch nodules (hyperpigmented iris hamartomas) may be seen in the eyes by slit lamp examination. Learning difficulties and skeletal dysplasia occur. Later on, fleshy skin tags and deeper soft tumours (neurofibromas) appear and they can progress to completely cover the skin causing significant cosmetic disability. A number of endocrine disorders are rarely associated including pheochromocytoma, acromegaly and Addison's disease.

Tuberous sclerosis (epiloia)

The tuberous sclerosis complex (TSC) is an autosomal dominant condition of variable severity which may not present until later childhood. It is characterized by a variety of hamartomatous growths. The three cardinal features are (1) mental retardation, (2) epilepsy and (3) cutaneous abnormalities – but not all have to be present. In most cases, it is due to a mutation in either the *TSC1* gene (encodes hamartin) or the *TSC2* gene (encodes tuberin). Genetic testing is available but the diagnosis still remains clinical, requiring two major features or one major and two minor features. The *skin signs* include:

- Adenoma sebaceum (reddish papules/fibromas around the nose)
- Periungual fibroma (nodules arising from the nail bed)
- Shagreen patches (firm, flesh-coloured plaques on the trunk)
- Ash-leaf hypopigmentation (pale macules best seen with UV light)
- Forehead plaque (indurated flesh-coloured patch)
- Café-au-lait patches
- Pitting of dental enamel.

Internal hamartomas can arise in the heart, lung, kidney, retina and CNS. Parents of a suspected case should be carefully examined (under UV light) as they may have a 'forme fruste' of the condition, which can manifest just as hypopigmented patches. This and gonadal mosaicism can have genetic implications for future offspring. A large contiguous gene defect may involve *TSC2* and *PKD1* genes causing tuberous sclerosis and polycystic kidney disease together in the same patient.

Diabetes mellitus

Diabetes mellitus (see also p. 1001) can have a number of cutaneous features. Complications of diabetes itself include:

- Fungal infection (e.g. *Candidiasis*)
- Bacterial infections (e.g. recurrent boils)
- Xanthomas
- Arterial disease (ulcers, gangrene)
- Neuropathic ulcers.

Specific dermatoses of diabetes include:

- Necrobiosis lipidica (a patch of spreading erythema over the shin which becomes yellowish and atrophic in the centre and may ulcerate)
- Diffuse granuloma annulare (p. 1212)
- Diabetic dermopathy (red-brown flat-topped papules)
- Blisters (usually on the feet or hands)
- Diabetic stiff skin (tight waxy skin over the fingers with limitation of joint movement owing to thickened collagen – also called cheiroarthropathy).

Necrobiosis lipidica on the shin in type 1 diabetes mellitus.

Chronic liver disease

Chronic liver disease may present with jaundice, palmar erythema, spider naevi, white nails, hyperpigmentation and pruritus.

Porphyria cutanea tarda (PCT, p. 1045) is a rare genetic disorder associated with liver disease usually due to hepatic damage from excessive alcohol consumption or hepatitis C infection. Some 75% of cases are sporadic, 25% familial. Overall, 20% of cases have underlying hereditary haemochromatosis (p. 303). PCT presents clinically on exposed skin with sun-induced blisters, skin fragility, scarring, milia and hypertrichosis. Treatment of the cutaneous features is with repeated venesection and/or very low-dose chloroquine plus avoidance of alcohol. There is anecdotal evidence that specific treatment of hepatitis C will also help the skin, presumably by improving liver function. All people with PCT are at risk of hepatic carcinoma.

Chronic kidney disease (CKD)

Chronic kidney disease (see also p. 320) is commonly associated with intractable pruritus. Pallor, hyperpigmentation and ecchymoses are commonly seen. Rarely it is associated with non-inflammatory blisters, pseudo-porphyria cutanea tarda and cutaneous calcification. Longstanding renal transplant patients often suffer with recurrent viral warts and squamous cell carcinomas due to the immunosuppression.

'Nephrogenic fibrosing dermopathy' (also known as 'nephrogenic systemic fibrosis') is a newly described severe scleroderma-like skin disease in a subset of patients who have CKD (usually on dialysis). The disease is rapid in onset (days to weeks) with skin discoloration and thickening, joint contractures, muscle weakness and generalized pain. Widespread tissue fibrosis may ensue, causing severe morbidity. Patients may rapidly become wheelchair-bound. The condition is strongly associated with the contrast medium gadolinium used in MRI scans, and such contrast agents are best avoided in people with low GFRs. There is no accepted treatment but some advocate PUVA and extracorporeal photophoresis. No spontaneous remissions have been recorded. Rapid correction of renal function generally stops the condition progressing.

Calciophylaxis is discussed in Chapter 12.

Thyroid disease (see also p. 937)

Hypothyroidism may cause dry firm gelatinous (myxoedematous) skin with diffuse hair thinning and loss of the outer third of the eyebrows. Hyperthyroidism may be associated with warm sweaty skin and a diffuse alopecia. Graves' disease is rarely associated with thyroid acropachy ('clubbing' with underlying bone changes) and pretibial myxoedema (a red-brown mucinous infiltration of the shins which can become lumpy and tender).

Cushing's syndrome (see also p. 957)

This may cause hirsutism, a moon face, a buffalo hump, stretchmarks (striae) and a pustular folliculitis (often called steroid acne) of the skin.

Hyperlipidaemias

Hyperlipidaemias (see also p. 1034) can present with xanthomas, which are abnormal collections of lipid in the skin. All people with xanthomas should be investigated for hyperlipidaemia although the most common type, called xanthelasma (yellow plaques around the eyes), are usually associated

with normal lipids. There are a number of other clinical variants of xanthomas such as (1) tuberous xanthoma (firm orange-yellow nodules and plaques on extensor surfaces); (2) tendon xanthoma (firm subcutaneous swellings attached to tendons); (3) plane xanthoma (orange-yellow macules often affecting palmar creases); (4) eruptive xanthoma (numerous small yellowish papules commonly on the buttocks).

Amyloidosis

Macular amyloid is a common purely cutaneous variant seen in Asians. It is characterized by itchy brown rippled macules on the upper back.

Systemic amyloid may be associated with reddish brown papules, nodules or plaques especially around the eyes, the flexural areas and mucosal surfaces. Distinctive periorbital bruising and macroglossia may also be present.

Systemic malignant disease

Certain rashes may be a non-metastatic manifestation of an underlying malignancy: paraneoplastic dermatoses (Table 24.12). Rarely tumours can metastasize to the skin where they normally present as papules or nodules which may proceed to ulcerate.

BULLOUS DISEASE

Primary blistering diseases of the skin are rare. A variety of skin proteins hold the skin together. Inherited abnormalities or immune damage of these proteins cause abnormal cell separation, inflammation, fluid accumulation and blistering (Fig. 24.27). The level of blistering determines the clinical picture as well as the prognosis. Therefore skin biopsy for light and electron microscopy together with immunofluorescence (IMF) studies is paramount in diagnosis. However, remember that the commonest causes of skin blistering are chickenpox, herpes, impetigo, pompholyx eczema and insect bite reactions, although the latter are often localized.

Immunobullous disease

Pemphigus vulgaris

Pemphigus vulgaris is a potentially fatal blistering disease occurring in all races but commoner in Ashkenazi Jews and possibly in people from the Indian subcontinent. Onset is usually in middle age and both sexes are affected equally. The development of autoantibodies, e.g. IgG₄ against the desmosomal protein desmoglein 1 and 3 is pathogenic in this disease and the autoantibodies can be measured as markers of disease activity. Desmoglein 1 and 3, an adhesion molecule, is expressed in skin and mucosal surfaces, so both will blister. Rarely the disease can be drug induced (e.g. penicillamine or captopril).

Skin biopsy shows a superficial intraepidermal split just above the basal layer with acantholysis (separation of individual cells). In the rarer variant, pemphigus foliaceus (characterized by anti-desmoglein 1 IgG₄ autoantibodies), the

Table 24.12 Non-metastatic cutaneous manifestations of underlying malignancy	
Dermatosis	Tumour
Dermatomyositis	Lung, GI tract, GU tract
Acanthosis nigricans	GI tract, lung, liver
Paget's disease (localized patch of eczema around the nipple)	Ductal breast carcinoma
Erythroderma	Lymphoma/leukaemia
Tylosis (thickened palms/soles)	Oesophageal carcinoma
Tripe palms (velvet palms)	Pulmonary, gastric
Ichthyosis (dry flaking of skin)	Lymphoma
Erythema gyratum repens (concentric rings of erythema, which change rapidly)	Lung, breast
Necrolytic migratory erythema (burning, geographic and spreading annular areas of erythema)	Glucagonoma

split is higher in the upper epidermis. As desmoglein 1 is not expressed in oral mucosa, only cutaneous blisters are seen in this subtype. Both direct IMF of skin (perilesional) and indirect IMF using patients' serum show intercellular staining of IgG within the epidermis.

Clinical features

Mucosal involvement (especially oral ulceration) is common and is the presenting sign in up to 50% of cases. This may then be followed by the appearance of non-itchy flaccid blisters, particularly involving the trunk. Blistering usually becomes widespread but they rapidly denude; thus pemphigus often presents with erythematous, weeping erosions. Blisters can be extended with gentle sliding pressure (Nikolsky's sign). Flexural lesions often have a vegetative appearance. In pemphigus foliaceus the blisters and erosions often start in a seborrhoeic distribution (scalp, face and upper chest) before becoming more widespread.

Treatment

This is with very high-dose oral prednisolone (60–100 mg daily) or pulsed methylprednisolone and is often needed lifelong. Therefore other immunosuppressants such as azathioprine or mycophenolate mofetil (or occasionally cyclophosphamide or ciclosporin) are used as steroid-sparing agents. Intravenous immunoglobulin infusions help gain quick control whilst waiting for these other drugs to work. The anti-B cell drug rituximab (anti-CD20 monoclonal antibody) is useful in multidrug-resistant cases.

Whilst treatment is normally effective, perhaps up to 10% of patients may die either due to complications of the disease or more commonly from side-effects of the treatment.

Bullous pemphigoid

Bullous pemphigoid is more common than pemphigus. It presents in later life (usually over 60) and mucosal involvement is rarer. Autoantibodies against a 230 kDa or 180 kDa hemidesmosomal protein ('bullous pemphigoid antigen 1' and 'type XVII collagen') play an aetiological role.

Skin biopsy shows a deeper blister (than in pemphigus) due to a subepidermal split through the basement membrane. Direct and indirect IMF studies show linear staining of IgG along the basement membrane.

Clinical features

Large tense bullae appear anywhere on the skin but often involve limbs (Fig. 24.28), hands and feet. The bullae may be centred on an erythematous or urticated background and they can be haemorrhagic. Pemphigoid can be very itchy. Mucosal ulceration is uncommon but a variant of pemphigoid

Linear IgA disease
– typical circular clustering of blisters.

Figure 24.28 Bullous pemphigoid.

exists which predominantly affects mucosal surfaces with scarring (mucous membrane pemphigoid).

Treatment

This is with high-dose oral prednisolone (30–60 mg daily) and steroid-sparing agents such as azathioprine or mycophenolate mofetil. Weekly methotrexate is also occasionally used. In general, disease control is easier than with pemphigus. Often treatment can be withdrawn after 2–3 years. Treatment often causes side-effects, especially as most patients are elderly. Occasionally localized or mild disease can be controlled with superpotent topical steroids, oral dapsone or high-dose oral minocycline.

Dermatitis herpetiformis

Dermatitis herpetiformis (DH) (see also p. 266) is a rare blistering disorder associated with gluten-sensitive enteropathy (coeliac disease). DH and coeliac disease are associated with other organ-specific autoimmune disorders. The HLA associations (B8, DR3, DQ2 in 80–90% of cases) and immunological findings (endomysial, tissue transglutaminase, reticulin and gliadin autoantibodies present in serum) are similar to coeliac disease.

Skin biopsy shows a subepidermal blister with neutrophil microabscesses in the dermal papillae. Direct immunofluorescent studies of uninvolved skin show IgA in the dermal papillae and patchy granular IgA along the basement membrane. The jejunal mucosa shows a partial villous atrophy.

Clinical features

Dermatitis herpetiformis is commoner in males and can present at any age but is most likely to appear for the first time in young adult life. It presents with small, intensely itchy blisters of the skin. The lesions have a predilection for the elbows, extensor forearms, scalp and buttocks. The tops of the blisters are usually scratched off; thus crusted erosions are often seen at presentation. Remissions and exacerbations are common.

Treatment

This should always be with a gluten-free diet (GFD, p. 266). Control of the skin disease can be obtained with oral dapsone (50–200 mg daily) or sulphonamides. If a strict GFD is adhered to, oral medication can often be withdrawn after 2 years.

Use of dapsone. Dapsone frequently causes a mild dose-related haemolytic anaemia (which is usually well tolerated) but the haemolysis can be devastating if there is G6PD deficiency. Liver damage, peripheral neuropathy and aplastic anaemia can also rarely occur so regular monitoring of a blood count and liver function is needed.

Linear IgA disease (chronic bullous dermatosis of childhood)

Linear IgA disease is a subepidermal blistering disorder of adults and children. Pathogenic IgA autoantibodies bind to a variety of basement membrane proteins including type XVII collagen and laminin-332 (see Fig. 24.27). It is the most common immunobullous disease seen in children. Rarely it is induced by vancomycin.

Clinical features

Linear IgA disease can present with circular clusters of large blisters, a pemphigoid type of blistering or a dermatitis herpetiformis picture. Mucosal involvement of the mouth, vulva

and eyes is not uncommon and can cause scarring. Direct IMF studies of skin show linear IgA deposition along the basement membrane.

Treatment

This is with oral dapsone (50–200 mg daily) or sulphonamides. Occasionally, immunosuppression is needed. Many patients show spontaneous resolution after 3–6 years.

Mechanobullous disease (epidermolysis bullosa, 'EB')

These are due to inherited abnormalities in structural skin proteins which lead to 'skin fragility'. The resultant blistering tends to arise secondary to trauma and often appears at or shortly after birth. These conditions can be a mild inconvenience, severely disabling or fatal but fortunately are very rare. There are three groups of disorders in which the fundamental gene/protein abnormalities have been characterized.

- **Epidermolysis bullosa simplex** is a group of autosomal dominant genodermatoses characterized by 'superficial' blistering owing to mutations of cytoskeleton proteins within the basal layer of the epidermis, e.g. keratin 5 (chromosome 12q) or keratin 14 (chromosome 17q). Most forms of EB simplex show mild disease with intermittent blistering of the hands and feet, especially in hot weather. The teeth and nails are normal and scarring is absent.
- **Epidermolysis bullosa dystrophica** is a group of genodermatoses characterized by 'deeper' blistering associated with scarring and milia formation. The level of split is deep within the basement membrane and is due to a mutation in the *COL-7A1* gene (locus at chromosome 3p21.1) which causes a loss of collagen VII in the anchoring fibrils. Nails, mucosae and even the larynx are often involved. The autosomal dominant variety is milder but the autosomal recessive type produces severe disease with painful disabling scarring, fusion of digits, joint contractures and dysphagia. Life expectancy is significantly reduced. Repeated scarring results in the development of multiple squamous cell carcinomas and most die from this complication in early adult life. The average life expectancy after the appearance of the first squamous cell carcinoma is 5 years. Stem cell transplantation is being used.
- **Junctional epidermolysis bullosa** is the most severe form. It is characterized by a split in the lamina lucida of the basement membrane and is due to mutations in various proteins, mainly laminin-332 but also $\alpha_6\beta_4$ integrin or type XVII collagen. It presents at birth with widespread blistering and areas of absent skin. Erosions of the central face and hoarseness from laryngeal involvement are common. Nail and teeth abnormalities are also common. Both a lethal and a rarer non-lethal form of junctional EB exist and they show an autosomal recessive inheritance. The lethal form causes death in infancy or early childhood.

Investigation and treatment

Investigation and treatment of EB should be carried out in a specialist centre. Exact diagnosis depends on ultrastructural analysis of induced blisters in the skin and immunohistochemistry, and these investigations can be further confirmed with genetic testing. Only then can prognosis and genetic counselling be given accurately to parents. Prenatal

diagnosis and preimplantation diagnosis is available for the more severe forms of EB. Gene therapy and bone marrow transplantation are two new approaches that are currently under assessment.

SKIN TUMOURS

Benign cutaneous tumours

Melanocytic naevi (moles)

Moles are a benign overgrowth of melanocytes that are common in white-skinned people. They appear in childhood and increase in number and size during adolescence and early adult life. They often start as flat brown macules with proliferation of melanocytes at the dermoepidermal junction (junctional naevi). The melanocytes continue to proliferate and grow down into the dermis (compound naevi) which causes an elevation of the mole above the skin surface. The pigmentation is usually even and the border regular. They eventually mature into a dermal naevus (cellular naevus), often with a loss of pigment.

Blue naevus is an acquired asymptomatic blue-looking mole. It is due to a proliferation of melanocytes deep in the mid-dermis.

Basal cell papilloma (seborrhoeic wart)

This is a common benign overgrowth of the basal cell layer of the epidermis. The lesion can be flesh coloured, brown or even black and often has a greasy appearance. The surface is irregular and warty and the lesions appear very superficial as though stuck on to the skin (Fig. 24.29). Tiny keratin cysts may be seen on the surface. They can be treated with cryotherapy or curettage.

Dermatofibroma (histiocytoma)

Dermatofibromas appear as firm, elevated pigmented nodules which may feel like a button in the skin. A peripheral ring of pigmentation is sometimes seen. They are often found on the leg and are commoner in females. There may be a preceding history of trauma or insect bite. The lesion consists of histiocytes, blood vessels and varying degrees of fibrosis. If symptomatic, excision is required.

Epidermoid cyst (previously 'sebaceous cyst')

Epidermoid cysts present as cystic swellings of the skin with a central punctum. They contain 'cheesy' keratin. These cysts occasionally rupture causing significant dermal inflammation.

Pilar cyst (trichilemmal cyst)

Pilar cysts are smooth cysts without a punctum usually found on the scalp. They may be multiple and familial.

Figure 24.29 Seborrhoeic warts (basal cell papillomas).

Keratoacanthoma

Keratoacanthomas are rapidly growing epidermal tumours which develop central necrosis and ulceration (Fig. 24.30). They occur on sun-exposed skin in later life and can grow up to 2–3 cm across. Whilst they may resolve spontaneously over a few months, they are best excised both to exclude a squamous cell carcinoma (which they can mimic) and to improve the cosmetic outcome.

Pyogenic granuloma (granuloma telangiectaticum)

Pyogenic granulomas are a benign overgrowth of blood vessels. They present as rapidly growing pinkish red nodules which are friable and readily bleed. They may follow trauma and are often found on the fingers and lips. They are best excised to exclude an amelanotic malignant melanoma.

Cherry angioma (Campbell de Morgan spots)

These are benign angiokeratomas that appear as tiny pinpoint red papules, especially on the trunk, and increase with age. No treatment is required.

Potentially pre-malignant cutaneous tumours

Solar keratoses (actinic keratoses)

These frequently develop later in life in white-skinned people who have had significant sun exposure. They appear on exposed skin as erythematous silver-scaly papules or patches with a conical surface and a red base (Fig. 24.31). The background skin is often inelastic, wrinkled and may show flat brown macules (solar lentigos) reflecting diffuse solar damage. A small proportion of these keratoses can transform into squamous cell carcinoma but only after many years.

Figure 24.30 Keratoacanthoma.

Figure 24.31 Solar keratoses with background actinic damage.

Treatment of lesions is with cryotherapy, topical 5-fluorouracil cream, 5% imiquimod cream or diclofenac gel.

Bowen's disease

This is a form of intraepidermal carcinoma-in-situ which rarely can become invasive. It is thought to be due to long-term sun exposure. It presents on exposed skin, most commonly women's legs, as an isolated scaly red patch or plaque looking rather like psoriasis although it has a rather irregular edge. The lesions do not clear but slowly increase in size with time.

A variant which can show partial or full-thickness dysplasia can involve the epidermis of the mucosa or neighbouring skin. This can affect the vulva, the glans penis and perianal skin and is termed vulval (penile, or anal) intraepithelial neoplasia. Clinically, it can present as nonspecific erythema or as a warty thickening. These diseases have a stronger link with HPV and probably have a higher pre-malignant potential than Bowen's disease. They are commoner in immunosuppressed individuals. The anal form is increasingly reported in HIV-positive patients (as indeed is anal carcinoma) and extension into the rectum may occur.

Treatment is with topical 5-fluorouracil, 5% imiquimod cream, cryotherapy, curettage, photodynamic therapy or a tissue-destructive laser.

Atypical mole syndrome (dysplastic naevus syndrome)

This is often familial. A large number of melanocytic naevi begin to appear in childhood even on unexposed sites. Individual lesions may be large with irregular pigmentation and border, and histologically they may show cytological and architectural atypia but no frank malignant change. Individuals with this condition have an increased risk of developing malignant melanoma. They should have their moles photographed and be regularly reviewed. Suspicious lesions should be excised.

Giant congenital melanocytic naevi

These are very large moles present at birth. Very large lesions (>20 cm across) show an increased risk of developing malignant melanoma (up to 5%). Excision may be considered but is rarely possible without multiple operations and marked disfigurement so regular monitoring is advised. There have been a number of reports showing that a few of these lesions improve spontaneously and partially resolve during childhood.

Lentigo maligna

This is a slow-growing macular area of pigmentation seen in elderly people, commonly on the face. The border and pigmentation are often irregular. Some people regard this lesion as a melanoma-in-situ. There is an increased risk of developing invasive malignant melanoma. Treatment is by excision if possible but 5% imiquimod cream is currently being tried in the very large lesions where surgery would be disfiguring.

Malignant cutaneous tumours

Basal cell carcinoma (rodent ulcer)

Basal cell carcinomas (BCC) are the most common malignant skin tumour but their relationship to excessive sun exposure is complex. Genotype and phenotype of the patient is also involved in pathogenesis. Multiple BCCs are seen in Gorlin's syndrome due to mutations in the PTCH1 gene and mutations in this gene have also been described in the sporadic form of BCC.

Erythroplasia of glans penis (penile intraepithelial neoplasia).

Figure 24.32 Ulcerating basal cell carcinoma.

BCCs are common later in life on exposed sites although rare on the ear. They are 10–20 times more common in the chronically immunosuppressed solid organ transplant population. They can present as a slow-growing papule or nodule (or rarely be cystic), which may go on to ulcerate (Fig. 24.32). Telangiectasia over the tumour or a skin-coloured jelly-like 'pearly edge' may be seen. A flat, diffuse superficial form exists as an ill-defined 'morphoeic' variant. Basal cell carcinomas will slowly grow and erode structures if untreated but these tumours almost never metastasize.

Treatment

Treatment is usually with surgical excision with controlled borders. Photodynamic therapy, cryotherapy, 5% imiquimod cream and rarely radiotherapy can be useful for large superficial forms but follow-up for recurrence is required. Curettage may occasionally be used in older patients although not for central facial lesions as they often recur. Recurrent tumour or morphoeic basal cell carcinoma is best treated with Mohs' micrographic surgery to ensure adequate clearance.

Squamous cell carcinoma

Squamous cell carcinoma (SCC) is a more aggressive tumour than basal cell carcinoma as it can metastasize if left untreated. Most relate directly to sun exposure, and daily application of sun cream has been shown to reduce the incidence in Australia. SCC can arise in pre-existing solar keratoses or Bowen's disease or be due to chronic inflammation such as in lupus vulgaris. Rarely multiple tumours may arise due to arsenic ingestion in early life. Multiple tumours also occur in people who have had prolonged periods of immunosuppression such as renal transplant patients where certain human papilloma virus subtypes may be involved in malignant transformation.

Clinically, the lesions are often keratotic, rather ill-defined nodules which may ulcerate (Fig. 24.33). They can grow very rapidly. Examination of regional lymph nodes is essential. They are most common on sun-exposed sites in later life. Ulcerated lesions on the lower lip or ear are often more aggressive.

Treatment

Treatment is with excision or occasionally radiotherapy. Curettage should be avoided.

Figure 24.33 Squamous cell carcinoma.

Table 24.13 Clinical criteria for the diagnosis of malignant melanoma

ABCDE criteria (USA):	
Asymmetry of mole	
Border irregularity	
Colour variegation	
Diameter >6 mm	
Elevation	
The Glasgow 7-point checklist:	
Major criteria	Change in size Change in shape Change in colour
Minor criteria	Diameter >6 mm Inflammation Oozing or bleeding Mild itch or altered sensation

Malignant melanoma

Malignant melanoma is the most serious form of skin cancer as metastasis can occur early and it causes a number of deaths even in young people. As with other types of skin cancer the incidence is continuing to increase, probably due to excessive exposure to sunlight. The history of childhood sun exposure and intermittent intense sun exposure appears to be necessary for the development of malignant melanoma. Other risk factors include pale skin, multiple melanocytic naevi (>50), sun sensitivity, immunosuppression, atypical mole syndrome, giant congenital melanocytic naevi, lentigo maligna and a positive family history of malignant melanoma. Malignant melanoma is commoner in later life but many young adults are also affected. A number of oncogenes and tumour suppressor proteins (CDK4, CDKN2a, B-RAF, PTEN, Ras, Rb, p53, p16) have been implicated in the pathogenesis of melanoma. Some 60% of human melanomas have an activating mutation (V600E) in the serine protein kinase B-RAF which has now become a target for 'personalized' therapy (p. 1226).

Diagnosis of melanoma is not always easy but the clinical signs listed in Table 24.13 help distinguish malignant from benign moles. Examination with a dermatoscope (a handheld polarized light source with magnification) can further help in detecting malignant lesions.

Figure 24.34 Nodular malignant melanoma.

Four clinical types exist:

- **Lentigo maligna melanoma** is where a patch of lentigo maligna develops a papule or nodule signalling invasive tumour.
- **Superficial spreading malignant melanoma** is a large flat irregularly pigmented lesion which grows laterally before vertical invasion develops.
- **Nodular malignant melanoma** (Fig. 24.34) is the most aggressive type. It presents as a rapidly growing pigmented nodule which bleeds or ulcerates. Rarely they are amelanotic (non-pigmented) and can mimic pyogenic granuloma.
- **Acral lentiginous malignant melanomas** arise as pigmented lesions on the palm, sole or under the nail and they usually present late. They may not be related to sun exposure.

Treatment

In the UK, all people with melanoma >1 mm thick should be referred to their regional multidisciplinary team for expert management. Surgery is the only curative treatment: urgent wide excision 1 cm margin for thin melanomas (<1 mm) increasing to 3 cm margin for thicker melanomas (>2 mm). Histological analysis will determine the depth of invasion ('Clark's level') and the thickness of the tumour ('Breslow thickness'). People with thick melanomas are staged according to the American AJCC 2009 criteria which look at tumour thickness, metastasis and lymph node status and this helps predict prognosis and 5-year survival rates. Sentinel node biopsy for people with thicker lesions is currently under assessment as a tool for predicting prognosis, determining therapy (e.g. lymph node dissection) and improving survival but it remains a research tool. Metastatic disease can involve surgery to lymph nodes, isolated limb perfusion, radiotherapy, immunotherapy and chemotherapy but no therapy in phase 3 trials has yet shown a significant increase in survival. Ipilimumab is showing early promise in selected people with metastatic disease. Vemurafenib is a potent kinase inhibitor with specificity for the BRAF V600E metastatic melanoma; 50% of patients respond, with an overall survival of 16 months.

Cutaneous T cell lymphoma (mycosis fungoides)

This is a rare type of skin tumour which often follows a relatively benign course. It presents insidiously with scaly patches and plaques which can look eczematous or psoriasiform. Lesions often appear initially on the buttocks. These lesions may come and go or remain persistent over many

years. Patients may well die of unrelated causes. Skin biopsy confirms the diagnosis, showing invasion by atypical lymphocytes. T cell receptor gene rearrangement studies show that there is often a monoclonal expansion of lymphocytes in the skin.

Occasionally the disease can progress to a cutaneous nodular or tumour stage, which may be accompanied by systemic organ involvement. In elderly males the disease may progress rarely to an erythrodermic variant accompanied by lymphadenopathy and peripheral blood involvement ('Sézary's syndrome').

All patients should be staged at the time of diagnosis to assess for any systemic involvement.

Treatment

Early cutaneous disease can be left untreated or treated with topical steroids or PUVA. More advanced disease of the skin, or systemic involvement, may require radiotherapy, oral retinoids (bexarotene), chemotherapy (e.g. methotrexate), immunotherapy or electron beam therapy. AntiCD4 and antiCD25 monoclonal antibodies are currently under assessment in advanced disease.

Kaposi's sarcoma

This is a tumour of vascular and lymphatic endothelium that presents as purplish nodules and plaques. There are three types:

- **The 'classic' or 'sporadic' form** (as described by Kaposi) occurs in elderly males, especially Jewish people from Eastern Europe. It presents as slow-growing purple tumours in the foot and lower leg which rarely cause any significant problem.
- **The 'endemic' form** occurs in males from central Africa and shows more widespread cutaneous involvement as well as lymph node (or occasionally systemic) involvement. Oedema is a prominent feature.
- **The immunosuppression-related form** is more severe and is most common in HIV-positive men who have sex with men. Lesions are widespread and often affect the skin, bowel, oral cavity and lungs.

All three types have a strong association with herpes virus type 8 but other factors must be involved as herpes type 8 seroprevalence is up to 10% in the USA and 50% in some African countries. HAART (p. 171) has significantly reduced the incidence of Kaposi's sarcoma in HIV infection although the prevalence has started to increase again over the last few years for as yet unexplained reasons.

Treatment

Treatment of advanced Kaposi's sarcoma is with radiotherapy, immunotherapy or chemotherapy.

DISORDERS OF BLOOD VESSELS/LYMPHATICS

Leg ulcers

Leg ulcers are common and can have many causes (Table 24.14). Venous ulcers are the most common type in developed countries.

Venous ulcers

Venous ulcers are the result of sustained venous hypertension in the superficial veins, owing to incompetent valves in

Table 24.14 Causes of leg ulceration

Venous hypertension
Arterial disease (e.g. atherosclerosis)
Neuropathic (e.g. diabetes, leprosy)
Neoplastic (e.g. squamous or basal cell carcinoma)
Vasculitis (e.g. rheumatoid arthritis, SLE, pyoderma gangrenosum)
Infection (e.g. ecthyma, tuberculosis, deep mycoses, Buruli ulcer, syphilis, yaws)
Haematological (e.g. sickle cell disease, spherocytosis)
Drug (e.g. hydroxycarbamide (hydroxyurea))
Other (e.g. necrobiosis lipoidica, trauma, artefact)

**Figure 24.35 Venous leg ulcer.**

the deep or perforating veins or to previous deep vein thrombosis. The increased pressure causes extravasation of fibrinogen through the capillary walls, giving rise to perivascular fibrin deposition, which leads to poor oxygenation of the surrounding skin.

Venous ulcers are common in later life and cause a significant drain on healthcare budgets as they are often chronic and recurrent; they affect 1% of the population over the age of 70 years. They are most commonly found on the lower leg in a triangle above the ankles (Fig. 24.35), and may be associated with:

- Oedema of the lower legs
- Venous eczema (p. 1206)
- Brown pigmentation from haemosiderin
- Varicose veins
- Lipodermatosclerosis (the combination of induration, reddish brown pigmentation and inflammation) – a fibrosing panniculitis of the subcutaneous tissue
- Scarring white atrophy with telangiectasia (atrophie blanche).

Treatment is with high-compression bandaging (e.g. four-layer bandaging) and leg elevation to try to decrease the venous hypertension. Doppler studies should always be done before bandaging to exclude arterial disease. This treatment is best delivered in the community by appropriately trained nurses. Ulcer dressings are used to keep the ulcer moist and free of slough and exudates. Up to 80% of ulcers can be healed within 26 weeks. Slower healing rates occur in patients who have decreased mobility and if the ulcers are very large, present for longer than 6 months or bilateral. Diuretics are sometimes helpful to reduce the oedema. Antibiotics are necessary only for overt bacterial infection.

Venous leg ulcers can be very painful so adequate analgesia should be given, including opiates if required.

Split-thickness skin grafting is used in resistant cases. Support stockings (individually fitted) should be worn lifelong after healing as this lessens recurrence.

Underlying venous disease is best investigated with duplex ultrasound or plethysmography. Therapeutic ultrasound is now proven not to help ulcer healing. Surgery for purely superficial venous disease does not help ulcer healing but it is proven to help prevent ulcer recurrence (ESCHAR study).

Arterial ulcers

Arterial ulcers present as punched-out, painful ulcers higher up the leg or on the feet. There may be a history of claudication, hypertension, angina or smoking. Clinically, the leg is cold and pale. Absent peripheral pulses, arterial bruits and loss of hair may be present. Doppler ultrasound studies will confirm arterial disease.

Treatment depends on keeping the ulcer clean and covered, adequate analgesia and vascular reconstruction if appropriate. Compression bandaging must not be used.

Neuropathic ulcers

Neuropathic ulcers tend to be seen over pressure areas of the feet, such as the metatarsal heads, owing to repeated trauma. These are most commonly seen in diabetics due to peripheral neuropathy. In some developing countries leprosy is a common cause.

Treatment depends on keeping the ulcer clean and removing pressure or trauma from the affected area. Diabetics should pay particular attention to foot care and correctly fitting shoes with the help of a specialist podiatrist (p. 1009).

Pressure sores (decubitus ulcers, bedsores)

These occur in the elderly, immobile, unconscious or paralysed patients. They are due to skin ischaemia from sustained pressure over a bony prominence, most commonly the heel and sacrum. Normal individuals feel the pain of continued pressure, and even during sleep movement takes place to change position continually. Pressure sores may be graded:

- Stage I: non-blanchable erythema of intact skin
- Stage II: partial-thickness skin loss of epidermis/dermis (blister or shallow ulcer)
- Stage III: full-thickness skin loss involving subcutaneous tissue but not fascia
- Stage IV: full-thickness skin loss with involvement of muscle/bone/tendon/joint capsule.

There are numerous risk factors for development of pressure sores (Table 24.15).

The majority of pressure sores occur in hospital. Some 70% appear in the first 2 weeks of hospitalization, and 70% are in orthopaedic patients, especially those on traction. Between 20% and 30% of pressure sores occur in the community. Some 80% of patients who have deep ulcers involving the subcutaneous tissue die in the first 4 months.

The early sign of red/blue discoloration of the skin can lead rapidly to ulcers in 1–2 hours. Leaving patients on hard emergency room trolleys, or sitting them in chairs for prolonged periods, must be avoided.

Management

Prevention

Prevention is better than cure. Specialist 'tissue-viability nurses' help identify at-risk patients and train other clinical staff. Several risk assessment tools have been devised for

the immobile patient based on the known risk factors. The 'Norton scale' and Waterlow Pressure Sore Risk Assessment (Box 24.4) are two such validated systems, which produce a numerical score, enabling staff to identify those at most risk. Braden, Walsall and Maelor scales are also used.

Treatment

- Bed rest with pillows and fleeces to keep pressure off bony areas (e.g. sacrum and heels) and prevent friction

Table 24.15	Risk factors for the development of pressure sores
Prolonged immobility	Paraplegia Arthritis Severe physical disease Apathy Operation and postoperative states Plaster casts Intensive care
Decreased sensation	Coma, neurological disease, diabetes mellitus Drug-induced sleep
Vascular disease	Atherosclerosis, diabetes mellitus, scleroderma, vasculitis
Poor nutrition	Anaemia Hypoalbuminaemia Vitamin C or zinc deficiency

- Air-filled cushions for patients in wheelchairs
- Special pressure-relieving mattresses and beds
- Regular turning but avoid pressure on hips
- Ensure adequate nutrition
- Non-irritant occlusive moist dressings (e.g. hydrocolloid)
- Adequate analgesia (may need opiates)
- Plastic surgery (debridement and grafting in selected cases)
- Treatment of underlying condition.

Vasculitis

Vasculitis (see also p. 542) is the term applied to an inflammatory disorder of blood vessels which causes endothelial damage. Cutaneous vasculitis (confirmed by skin biopsy) may be an isolated problem but occasionally is associated with vasculitis in other organs. The most commonly used classification is based on the size of blood vessel involved (see Tables 11.19 and 11.20).

The cutaneous features are of haemorrhagic papules, pustules, nodules or plaques which may erode and ulcerate. These purpuric lesions do not blanch with pressure from a glass slide ('diascopy'). Occasionally, a fixed livedo reticularis pattern may appear which does not disappear on warming. Pyrexia and arthralgia are common associations even in the absence of significant systemic involvement. Other clinical features depend on the underlying cause.

Leucocytoclastic vasculitis (LCV) or angitis is the most common cutaneous vasculitis affecting small vessels. This

usually appears on the lower legs as a symmetrical palpable purpura. It is rarely associated with systemic involvement. It can be caused by drugs (15%), infection (15%), inflammatory disease (10%) or malignant disease (<5%) but often no cause is found (55–60%). Investigations are only necessary with persistent lesions or associated signs and symptoms. Whilst LCV often settles spontaneously, treatment with analgesia, support stockings, dapsone or prednisolone may be needed to control the pain and to heal up any ulceration. *Urticarial vasculitis* is discussed on [page 1211](#).

Calciophylaxis (*calcific uraemic arteriopathy*) is described in [Chapter 12](#).

Lymphatics

Lymphoedema

Lymphoedema refers to a chronic non-pitting oedema due to lymphatic insufficiency. It is most commonly seen affecting the legs and tends to progress with age. The legs can become enormous and prevent wearing of normal shoes. Chronic disease may cause a secondary 'cobblestone' thickening of the skin. Lymphoedema can be primary (and present early in life) due to an inherited deficiency of lymphatic vessels (e.g. Milroy's disease) or can be secondary due to obstruction of lymphatic vessels (e.g. filarial infection or malignant disease).

Treatment is with compression stockings and physical massage. If there is recurrent cellulitis, long-term antibiotics are advisable as each episode of cellulitis will further damage the lymph vessels. Surgery should be avoided.

Lymphangioma circumscriptum

This is a rare hamartoma of lymphatic tissue. It usually presents in childhood with multiple small vesicles in the skin which weep lymphatic fluid and sometimes blood. They reflect deeper vessel involvement so surgery should be avoided. Cryotherapy or CO₂ laser treatment may help the superficial lesions.

DISORDERS OF COLLAGEN AND ELASTIC TISSUE

Ehlers–Danlos syndrome (see also [p. 559](#))

Ehlers–Danlos syndrome (EDS) can be subdivided into at least 10 variants. They are all inherited disorders causing abnormalities in collagen of the skin, joints and blood vessels. Clinically this causes increased elasticity of the skin, hypermobile joints (6–9 on the Beighton scale; see [Box 11.19](#)) and fragile blood vessels causing easy bruising or in some cases internal haemorrhage. The skin is hyperextensible but recoils normally after stretching. It is easily injured and heals slowly with scarring like tissue paper. Pseudotumours may occur at the sites of scarring (such as elbows and knees) consisting mainly of fat, but calcification can occur.

Pseudoxanthoma elasticum

Pseudoxanthoma elasticum is a rare disease characterized by abnormal mineralization of collagen and elastic tissue primarily affecting the skin, eye and blood vessels. It is caused by mutations in the cell transporter gene ABCC6. The phenotype can vary enormously and this may be dependent on the site of the mutation. The skin may be loose, lax and wrinkled. It can look yellowish and papular ('plucked chicken

Figure 24.36 Keloid scar of the lobe of the ear.

skin') and tends to lose its elastic recoil when stretched. Skin changes are best seen in the flexures, especially the sides of the neck. Non-cutaneous features are not always present but they include recurrent gastrointestinal bleeding, early myocardial infarction, claudication and angiod streaks on the retina reflecting disruption of vascular elastic tissue.

Striae

Striae are visible linear scars due to dermal collagen damage and stretching. Histologically a thinned epidermis overlies parallel bundles of fine collagen. They occur commonly over the abdomen and breasts in pregnancy but also occur on the thighs and trunk in rapidly growing adolescents as well as in some obese individuals. They are also seen in Cushing's syndrome and corticosteroid therapy. They are also rarely seen in Marfan's syndrome. Striae are initially reddish blue but fade to white atrophic marks. Puberty-related striae normally disappear completely.

Keloid scars

Keloid scars are characterized by smooth hard nodules ([Fig. 24.36](#)) due to excessive collagen production. They may occur spontaneously or follow skin trauma/surgery and they are often itchy. They tend to affect young adults and are much commoner in black Africans. Sites of predilection include the shoulders, upper back and chest, earlobes and chin. Unlike hypertrophic scars (which fade within 12 months) keloids are persistent and may continue to enlarge.

Treatment is with triamcinolone injection, compression with silica gels or surgery, but surgery must be followed by steroid injection or superficial radiotherapy or it may make the problem worse.

DISORDERS OF PIGMENTATION

Hypopigmentation

Vitiligo

Vitiligo is a common autoimmune disorder of depigmentation due to areas of melanocyte loss. Sufferers often have relatives with other organ-specific autoimmune disorders. It

Disorders of collagen and elastic tissue

Whitton ME, Ashcroft DM, Barrett CW et al. Interventions for vitiligo. *Cochrane Database Syst Rev* 2006; 25:CD003263.

presents in childhood or early adult life with well-demarcated macules of complete pigment loss. There is no history of preceding inflammation. Patients are very susceptible to sunburn. Lesions are often symmetrical and frequently involve the face, hands and genitalia (Fig. 24.37). The hair can also depigment. Trauma may induce new lesions. Spontaneous repigmentation can occur and often starts around hair follicles, giving a speckled appearance. However, repigmentation is rare if a lesion has persisted for more than 1 year or if the hair is depigmented.

Treatment is often unsatisfactory and has no impact on the long-term outcome. Sunblocks should be used to prevent burning. Potent topical steroids or phototherapy may help some individuals. Tacrolimus ointment (0.1%) can be a useful therapy in some individuals, especially on the face. If vitiligo is almost universal and fixed, depigmentation with monobenzone can be used. Finally, referral to a specialist camouflage clinic is often the most helpful 'treatment'.

Post-inflammatory hypopigmentation

This is one of the most common causes of pale skin. It is much more common in people with pigmented skin. It may be seen as a consequence of eczema, acne or psoriasis and may even be the reason for individuals presenting to a doctor. Providing the skin disease is controlled the pigmentation will recover slowly after many months. Post-inflammatory hyperpigmentation can also occur.

Oculocutaneous albinism

This is a group of rare autosomal recessive disorders affecting the pigmentation of skin, hair and eyes. It can affect all races. Melanocytes are normal in number but have abnormal function. Clinically it presents with universal pale skin, white or yellow hair and a pinkish iris. Photophobia, nystagmus and a squint are also present in most cases.

Treatment involves obsessive protection against sunlight to avoid sun burning and development of skin cancer.

Idiopathic guttate hypomelanosis

This occurs most commonly in black African people and is of unknown aetiology. It presents with small (2–4 mm) asymptomatic porcelain-white macules, often on skin exposed to sunlight. The borders are often sharply defined and angular. There is no effective treatment.

Leprosy (see also p. 130)

Both tuberculoid leprosy and indeterminate leprosy can present with anaesthetic patches of depigmentation and

should always be considered in people from endemic regions. Loss of hair and decreased sweating may also be present in the lesions.

Hyperpigmentation

Freckles (ephelides)

These appear in childhood as small brown macules after sun exposure. They fade in the winter months.

Lentigos

These are a more permanent macule of pigmentation similar to freckles but they tend to persist in the winter. Solar lentigos (also called 'liver spots') occur in older people on exposed skin due to actinic damage.

Chloasma (melasma)

These are brown macules often seen symmetrically over the cheeks and forehead and are most common in women. Chloasma can occur spontaneously but it is also associated with pregnancy and the oral contraceptive pill.

Metabolic/endocrine effects

A generalized skin darkening can occur with chronic liver disease, especially haemochromatosis. It also is seen sometimes in Cushing's syndrome, Addison's disease (more marked in palmar creases and buccal mucosa) and Nelson's syndrome.

Peutz-Jeghers syndrome (p. 271)

This is an autosomal dominant condition which presents with brown macules of the lips and perioral region. It is associated with gastrointestinal polyposis.

Urticaria pigmentosa (cutaneous mastocytosis)

This presents most commonly with multiple pigmented macules in children. These lesions tend to become red, itchy and urticated if they are rubbed (Darier's sign). Occasionally lesions may blister, and in the rare congenital, diffuse form of the disease the skin may become thickened and leathery. Occasionally systemic symptoms are present such as wheeze, flushing, syncope or diarrhoea, reflecting extensive mast cell degranulation from the skin. Anaphylaxis occurs very rarely and may be precipitated by mast cell degranulators such as aspirin or opiates. The condition spontaneously resolves after some years in children but is persistent in adults.

Skin biopsy shows an excess of mast cells in the skin. A mutation in the proto-oncogene *c-kit* often underlies the condition resulting in mast cell proliferation and mast cell apoptosis. Rarely there may be infiltration of internal organs with mast cells (*systemic mastocytosis*), especially in adult disease or neonatal disease. This can involve any organ but especially the bone (where it can cause severe pain), gastrointestinal tract, liver and spleen. There is a small risk of developing leukaemia if the bone marrow is heavily infiltrated.

Treatment of the skin, if required, is with antihistamines, sodium cromoglicate or PUVA as well as avoidance of opiates and NSAIDs.

Other conditions with pigmentation

Café-au-lait macules are seen in neurofibromatosis types 1 and 2, tuberous sclerosis, ataxia telangiectasia, Fanconi's anaemia, multiple endocrine neoplasia type 1 and McCune-Albright syndrome.

Multiple lentiginos are seen in Peutz-Jeghers syndrome, xeroderma pigmentosum, LEOPARD syndrome (Lentiginos,

Electrocardiographic conduction abnormalities, Ocular hyper-telorism, Pulmonary stenosis, Abnormalities of genitalia, Retardation of growth, Deafness) and Carney complex (lentiginosis, myxomas of heart and skin, endocrine overactivity).

Acquired melanocytic naevi are seen in Turner's syndrome (p. 978) and atypical mole syndrome (dysplastic naevus syndrome, p. 1224).

DRUG-INDUCED RASHES

Drugs can be toxic and teratogenic but they can also cause problems through allergic reactions. This frequently presents in the skin where just about any type of skin rash can arise (Table 24.16) although a widespread symmetrical maculopapular rash is the most common type (Fig. 24.38). 'Fixed drug eruptions' occur where a rash evolves and resolves at a specific site. The rash is reproduced at exactly the same site after a repeated exposure.

Table 24.16	Morphological types of drug rashes and some common causes
Maculopapular	Penicillin/amoxicillin
Urticaria	Penicillin, aspirin
Vasculitis	Gold, hydralazine
Fixed drug rash	Phenolphthalein in laxatives, tetracyclines, paracetamol
Pigmentation	Minocycline (black), amiodarone (slate grey)
Lupus erythematosus	Penicillamine, isoniazid
Photosensitivity	Thiazides, chlorpromazine, sulphonamide, amiodarone
Pustular	Carbamazepine
Erythema nodosum	Sulphonamide, oral contraceptive
Erythema multiforme	Barbiturates, etravirine
Acneiform	Corticosteroids
Lichenoid	Chloroquine, thiazides, gold, allopurinol
Psoriasiform	Methyldopa, gold, lithium, beta-blockers
Toxic epidermal necrolysis	Penicillin, co-trimoxazole, carbamazepine, NSAIDs, nevirapine, efavirenz
Pemphigus	Penicillamine, ACE inhibitors
Erythroderma	Gold, sulfonylureas, allopurinol, nevirapine, efavirenz

Figure 24.38 Morbilliform drug rash due to penicillin allergy.

The history is of great value in assessing drug reactions as a drug cause is very common. The use of prick testing and patch testing is rarely helpful and not without risk. Drug allergy can only be proven by rechallenging but this is rarely justified as it carries some risks. Rechallenging is occasionally justified for antituberculosis drugs or antiretroviral drugs but this should be carried out under medical supervision as there is a risk of anaphylaxis. Certain individuals (e.g. those with HIV infections) are more susceptible to drug rashes (Fig. 24.39).

Most rashes will settle spontaneously once the offending agent is removed. The commonest culprits in a hospital setting are antibiotics and chemotherapy agents. The three most serious types of drug rashes are:

- Erythroderma (p. 1215)
- Toxic epidermal necrolysis
- Drug-induced hypersensitivity syndrome.

Toxic epidermal necrolysis

This is characterized by widespread subepidermal blistering and sloughing of more than 30% of the skin and a high mortality (30–50%). A prodrome of cough, myalgia and anorexia may precede skin signs by 2–3 days. The skin may be itchy but typically takes on a burning quality. Fever and mucosal involvement are common. The internal epithelial surfaces (lung, bladder, gastrointestinal tract) are also involved. Multiorgan failure and sepsis often occur. Toxic epidermal necrolysis (TEN) can be fatal even after drug withdrawal and intensive care support. Patients should be managed in intensive care or a specialized burns unit. All drugs where possible should be withdrawn. Occlusive cutaneous dressings significantly reduce the pain, and an ophthalmological assessment and oral hygiene are necessary. Specific medical treatment with steroids or ciclosporin is controversial and rarely used. Intravenous immunoglobulin may be beneficial if given early in the disease and this is more commonly used.

A variant exists called *Stevens–Johnson syndrome* (SJS) where the damage is restricted to the mucosal surfaces with milder bullous involvement of the skin (<10%). Both SJS and

Figure 24.39 Erythema nodosum in a patient with HIV on co-trimoxazole.

TEN are commoner in slow acetylators and very much commoner in those with HIV infection.

Drug-induced hypersensitivity syndrome (DHS)

Also called '*anticonvulsant hypersensitivity syndrome*', 'drug reaction with eosinophilia and systemic symptoms', this is a serious adverse systemic reaction to a drug typically occurring 2–6 weeks after initial exposure. It is characterized by a generalized mucocutaneous rash, fever and lymphadenopathy with variable arthralgia, pharyngitis, periorbital oedema and hepatosplenomegaly. Rarely pustulation of the skin and conjunctivitis are present. The blood may show a peripheral eosinophilia, lymphocytosis with atypical lymphocytes, and a hepatitic picture. It can progress to multiorgan failure.

The cause of DHS is unknown but it may in part be due to genetic deficiency of epoxide hydrolase, a hepatic enzyme that detoxifies the arene oxide metabolites of antiepileptic drugs. There have been a number of reports about reactivation of various herpes family viruses (HHV 6 and 7, CMV, EBV) associating with DHS, the significance of which remains unclear. DHS can occur with any drug but a common culprit is one of the aromatic anticonvulsants (carbamazepine, phenytoin, phenobarbital, primidone and clonazepam) and as they can cross-react all these drugs must be avoided in the future. Sodium valproate is a suitable alternative. There is also potential for cross-reaction with the newer anticonvulsants vigabatrin and lamotrigine. Treatment is with drug withdrawal, systemic steroids and supportive care.

DISORDERS OF NAILS

Psoriasis and fungal nail infection are the commonest causes of nail dystrophy and are discussed above.

- **Nail pitting** can be caused by psoriasis, alopecia areata and atopic eczema. A few pits can be present due to trauma.
- **Onycholysis** (distal nail plate separation) is caused by psoriasis, thyrotoxicosis, following trauma and rarely due to a photosensitive reaction to drugs such as tetracyclines.
- **Koilonychia** (thin spoon-shaped nails) can be caused by iron deficiency anaemia or rarely be congenital.
- **Leuconychia** (white nails) is seen in hypoalbuminaemia. A striate congenital leuconychia exists.
- **Beau's lines** (transverse lines) appear as solitary depressions which grow out slowly over many months. They arise due to a severe illness or shock which causes a temporary arrest in nail growth.
- **Yellow-nail syndrome** is a rare disorder of lymphatic drainage. It presents with thickened, slow-growing, yellow nails which may be associated with pleural effusions, bronchiectasis and lymphoedema of the legs.
- **Onychogryphosis** is a gross thickening of the nail which is seen in later life, especially in the big toe-nail. There is often a history of preceding trauma. Both psoriasis and fungal infection can also cause nail thickening.
- **Nail-patella syndrome** is an autosomal dominant condition which presents with triangular rather than half-moon-shaped lunulae, especially of the thumb and forefingers. The nail plates may be small or dystrophic. The patellae are hypoplastic or absent. Other skeletal anomalies may be present and renal impairment (glomerulonephritis) occurs in up to 30% of individuals.

Table 24.17 Causes of alopecia

Scarring alopecia	Non-scarring alopecia
Discoid lupus erythematosus	Androgenic alopecia
Kerion (tinea capitis)	Telogen effluvium
Lichen planus	Alopecia areata
Dissecting cellulitis	Trichotillomania (self-induced hair-pulling)
X-irradiation	Tinea capitis
Idiopathic ('pseudopelade')	Traction alopecia
	Metabolic (iron deficiency, hypothyroidism)
	Drug (e.g. heparin, isotretinoin, chemotherapy)

- **Melanonychia** (longitudinal brown streaks) may be seen as a normal variant in black-skinned patients. In a white patient, it may reflect an underlying subungual melanoma, especially if the pigmentation progresses proximally onto the nail fold ('Hutchinson's sign').
- **Clubbing** is discussed in [Chapter 15](#).

DISORDERS OF HAIR

Hair loss

Hair loss can be due to a disorder of the hair follicle in which the scalp skin looks normal (non-scarring alopecia) or due to a disorder within the scalp skin that causes permanent loss of the follicle (scarring or cicatricial alopecia). This latter form causes shiny atrophic bald areas in the scalp which are devoid of follicular openings. There are many causes of alopecia ([Table 24.17](#)).

Androgenic alopecia

Androgenic alopecia (male pattern baldness) is the most common type of non-scarring hair loss and depends on genetic factors and an abnormal sensitivity to androgens. It presents in young men with frontal receding followed by thinning of the crown, and there is often a positive family history. It also occurs in females but tends to occur at a later age, be milder and show little in the way of frontal recession. If acne and menstrual disturbance are also present, the cause may be polycystic ovary syndrome or another endocrine disorder of androgens.

Treatment may not be required. Topical 5% minoxidil lotion or oral finasteride (1 mg daily) can help arrest progression and may cause a small amount of regrowth, providing it is used early in disease, but the treatment needs to be continued possibly lifelong. Approximately one-third of patients will not respond to either therapy. Finasteride is a selective inhibitor of 5 α -reductase type II and it can cause side-effects in 1% of patients such as loss of libido. It should not be used in females as it can affect the sexual development of a male fetus. However, antiandrogen therapy (e.g. cyproterone acetate or spironolactone) may help some women.

Alopecia areata

Alopecia areata may be regarded as an immune-mediated type of hair loss associated with other organ-specific autoimmune diseases. It presents in children or young adults with patches of baldness ([Fig. 24.40](#)). These may regrow to be followed by new patches of hair loss. The presence of broken

Figure 24.40 Alopecia areata.

exclamation mark hairs (narrow at the scalp and wider and more pigmented at the tip) at the edge of a bald area is diagnostic. Regrowth may initially be with white hairs and often occurs slowly over months. Occasionally all of the scalp hair is lost (alopecia totalis) and rarely all body hair is lost (alopecia universalis). The nails may be pitted or roughened.

Treatment has no effect on the long-term progression. Potent topical or injected steroids may be of limited use. Topical immunotherapy with diphencyprone, PUVA or topical 5% minoxidil is occasionally tried but often does not help. Wigs can be provided for severe cases and patient support groups are often beneficial.

Other disorders

Traction alopecia

This refers to the 'mechanical damage' type of hair loss that arises from pulling the hair back into a bun or tight plaiting. It is more common in black Africans.

Telogen effluvium

Telogen effluvium refers to the pattern of diffuse hair loss that occurs some 3 months after pregnancy or a severe illness. It occurs because 'stress' puts all the hairs into the telogen phase of hair shedding at the same time. The hair fully recovers and the normal staggered hair growth/hair shedding cycle resumes within a few months.

Dissecting cellulitis

This is a chronic folliculitis affecting predominantly young black males. It presents with papules and pustules over the occipital region of the scalp with hair loss. If severe, the back of the scalp becomes a boggy swelling (discharging pus) with areas of scarring alopecia. It can be complicated by keloid scar formation ('acne keloidalis nuchae').

Treatment is difficult but prolonged courses of low-dose antibiotics are worth trying in early disease. Prolonged courses of isotretinoin can help a few individuals and deep surgical excision can be used in recalcitrant cases. Combined rifampicin and clindamycin (both 300 mg \times 2) can be used in resistant cases.

Increased hair growth – hirsutism

Hirsutism (p. 979) refers to the male pattern of hair growth seen in females. The racial variation in hair growth must be considered. Certain races (e.g. Mediterranean and Asian) have more male pattern hair growth than northern European females. This is not due to excess androgens but may reflect

a genetically determined altered sensitivity to them. If virilizing features (deep voice, clitoromegaly, dysmenorrhoea, acne) are present, a full endocrine assessment is necessary. Hirsutism can cause severe psychological distress in some individuals.

Treatment involves physical methods such as bleaching, waxing, electrolysis, photoepilation and laser therapy. Anti-androgen therapy is occasionally helpful.

Hypertrichosis

Hypertrichosis refers to the state of excessive hair growth at any site and occurs in both sexes. It can be seen in anorexia nervosa, porphyria cutanea tarda and underlying malignancy, and is caused by certain drugs (e.g. ciclosporin, minoxidil).

BIRTH MARKS/NEONATAL RASHES

Infantile haemangioma (strawberry naevus, cavernous haemangioma)

Infantile haemangioma affects up to 1% of infants. It presents at, or shortly after birth as a single red lumpy nodule that grows rapidly for the first few months. Multiple lesions can be present. They will spontaneously resolve with good cosmesis but may take up to 7 years for complete resolution. Occasionally plastic surgery is needed after resolution to remove residual slack skin. Reassurance of parents is usually all that is required.

Urgent treatment is indicated if:

- the lesion interferes with feeding or vision
- the lesion ulcerates or bleeds frequently
- the lesion is associated with high-output cardiac failure from shunting of large volumes of blood
- the lesion consumes platelets and/or clotting factors causing potentially life-threatening haemorrhage ('Kasabach–Merritt syndrome').

The last two complications are very rare and only tend to occur in large lesions with significant deep vessel involvement.

Treatment has been revolutionized by the discovery in France that oral propranolol (2 mg/kg per day in 3 divided doses) rapidly shrinks these haemangiomas even the deep or sub-glottic lesions. High-dose systemic steroids, vincristine or embolization are rarely used for non-responding patients.

Port-wine stain (naevus flammeus)

Port-wine stain is also called a capillary haemangioma but strictly speaking it is not a haemangioma, just an abnormal dilation of dermal capillaries. It presents at birth as a flat red macular area and is commonly found on the face. It does not improve spontaneously and it may become thickened with time. If the lesion is found in the distribution of the first division of the trigeminal nerve it may be associated with ipsilateral meningeal vascular anomalies that can cause epilepsy and even hemiplegia (Sturge–Weber syndrome). If a port-wine stain involves the skin near the eye, glaucoma is a risk and ophthalmic assessment is mandatory.

Treatment of port-wine stains is ideally with the tunable dye (pulsed dye) laser. Facial lesions respond best but lesions can re-darken after some years.

Dissecting cellulitis of scalp in an African Caribbean male.

Urticaria pigmentosa (mastocytosis) and Mongolian blue spots in a baby.

Other conditions in the newborn

Milia

'Milk spots' are small follicular epidermal cysts. They are small pinhead white papules commonly found on the face of infants. They resolve spontaneously, unlike in adults.

Mongolian blue spot

This appears in infants as a deep blue-grey bruise-like area, usually over the sacrum or back. It is occasionally mistaken as a sign of child abuse. It is due to deep dermal melanocytes. It is very common in Oriental children, less common in black Africans and rare in Caucasians. It has usually disappeared by the age of 7 years.

Toxic erythema of the newborn (erythema neonatorum)

Toxic erythema of the newborn is a term used to describe a common transient blotchy maculopapular rash in newborns. The rash is occasionally pustular but the child is not toxic or unwell. It disappears spontaneously within a few days.

Nappy rash ('diaper dermatitis')

This is an irritant eczema caused by occlusion of faeces and urine against the skin. It is almost universal in babies. The flexures are usually spared, which is a useful differentiating feature from seborrhoeic and atopic eczema. If satellite lesions are present around the edge it may indicate a superimposed *Candida* infection. This rash can also occur in the elderly incontinent.

Treatment involves frequent changing of the nappy and regular application of a barrier cream.

Acrodermatitis enteropathica (p. 213)

This is due to a rare inherited deficiency of zinc absorption. It presents 4–6 weeks after weaning or earlier in bottle-fed babies. There is an erythematous, sometimes blistering, rash around the perineum, mouth, hands and feet. It may be associated with photophobia, diarrhoea and alopecia.

Treatment is with lifelong oral zinc, which seems to override the poor absorption. The response is rapid.

HUMAN IMMUNODEFICIENCY VIRUS AND THE SKIN

HIV infection (p. 171) commonly causes significant dermatological problems and a rash may even be the presenting feature of underlying HIV infection. These rashes can often be clinically atypical and difficult to diagnose, and skin biopsy and skin culture is sometimes required for diagnosis. Many of the skin problems are resistant to standard treatments, but HAART (p. 171) has decreased the prevalence.

Cutaneous infection and opportunistic infection are increased due to HIV-induced immune deficiency. *Molluscum contagiosum* is particularly common, especially on the face. Lesions are often multiple and of a 'giant' size measuring over 1 cm across. Molluscum is rarely seen in immunocompetent adults but can be the presenting feature of HIV. Other viral infections such as extensive ulcerative herpes or widespread viral warts are seen. Bacterial infections (e.g. staphylococcal boils) and fungal infections (e.g. ringworm and *Candida*) are also common. Recalcitrant and recurrent oropharyngeal candidiasis is a particular problem.

Opportunistic infections such as cutaneous cytomegalovirus (pustules or necrotic ulcers), sporotrichosis (linear

nodules) or *Cryptococcus* (red papules, psoriasiform or molluscum-like lesions) can pose diagnostic difficulties, stressing the need for skin biopsy and culture.

Inflammatory dermatoses show an increased incidence with HIV infection, probably due to an immune dysfunction or imbalance. Severe, *extensive seborrhoeic eczema* is very common and is often a presenting sign of HIV. Ichthyosis (dry scaly skin), nodular prurigo, pruritus and psoriasis are all more common in HIV infection and can be very severe. The treatment of these conditions can be difficult in patients who have low CD4 counts ($<200/\text{mm}^3$), as oral immunosuppressive therapies (e.g. prednisolone, ciclosporin) are best avoided. Topical therapies and phototherapy seem relatively safe and oral retinoids are a safe option for psoriasis.

'Autoimmune dermatoses' such as bullous pemphigoid, thrombocytopenic purpura and vitiligo seem to be increased in incidence. The aetiology is related to polyclonal stimulation of B lymphocytes by HIV with a resulting abnormal antibody production. *Erythroderma* is sometimes seen in HIV disease where skin biopsy suggests a 'graft-versus-host disease' mechanism. This presumably reflects a severe underlying immune dysfunction of T lymphocyte control.

Adverse drug rashes are much commoner in HIV patients. Reactions to co-trimoxazole, dapsone (used in *Pneumocystis* prophylaxis) and antiretroviral drugs appear particularly common. Drug rashes may be severe (especially with nevirapine and efavirenz), resulting in erythroderma or toxic epidermal necrolysis. Other unusual rashes include a striking nail/mucosal pigmentation from zidovudine, paronychia from indinavir and facial lipodystrophy mostly from protease inhibitors.

Cutaneous tumours. Benign tumours such as extensive persistent viral warts and melanocytic naevi are more common with HIV infection. Pre-malignant conditions such as the intraepithelial dysplasias (cervix CIN, penis PIN, anal AIN) are all much increased possibly due to persistent HPV infection. The risk of malignant transformation in all these three sites is high and should be screened for.

Kaposi's sarcoma (p. 1226) is much commoner in men who have sex with men with HIV than other groups. Basal and squamous cell carcinomas are also increased in incidence, presumably reflecting a loss of immune surveillance.

Interestingly, HAART has had little impact on reducing rates of anal, penile or cervical cancer and although Kaposi's sarcoma seemed to almost disappear early on when CD4 counts rose it now has shown a resurgence recently even in those with high CD4 counts and fully suppressed virus.

'Specific' HIV dermatoses

'Itchy folliculitis' of HIV

Itchy folliculitis (also called papular pruritic eruption) is common in HIV as CD4 counts decline. Its aetiology is unknown. The previously described staphylococcal folliculitis, eosinophilic folliculitis, pityrosporum folliculitis, and demodex mite folliculitis are probably all part of a spectrum and the term 'itchy folliculitis' is useful to encompass these. It presents with intensely itchy papules centred on hair follicles and occurring most commonly over the upper trunk and upper arms (Fig. 24.41). The face is more commonly involved in black patients. Individual lesions frequently have the top scratched off, leaving a crateriform appearance. **Treatment** with oral minocycline, potent topical steroids and emollients help. Phototherapy or oral isotretinoin is useful in resistant cases.

Figure 24.41 Itchy folliculitis of HIV infection on upper trunk and proximal limbs.

Oral hairy leucoplakia

This is characterized by white plaques with vertical ridging on the sides of the tongue. Unlike with oral *Candida* the lesions cannot be peeled off. It was first recognized in HIV disease but can rarely occur in other forms of immunosuppression. It is thought to be due to co-infection with Epstein-Barr virus.

Treatment is with aciclovir, ganciclovir or foscarnet.

Immune reconstitution inflammatory syndrome (IRIS)

Many infections can 'newly' present 2–4 months into HAART as CD4 counts are rising: so-called IRIS. Most commonly described are ano-genital HSV, viral warts, tinea folliculitis, molluscum and genital warts. It occurs in up to 25% of patients on HAART. It may simply reflect that the recovering immune system can now react against pathogens that were already present.

DERMATOSES OF PREGNANCY

There are a number of minor skin changes during pregnancy. There is an increase in spider naevi, melanocytic naevi, skin tags and chloasma. The abdomen shows midline pigmentation (linea nigra) and striae (stretch marks). There are four less common skin problems associated with pregnancy.

Polymorphic eruption of pregnancy (PEP, also called 'pruritic urticarial papules and plaques of pregnancy')

This rash tends to appear in the last trimester of a first pregnancy in 1 in 160 cases. It is of unknown aetiology and recurs only rarely in subsequent pregnancies. It presents with very itchy urticated papules and plaques and occasionally small vesicles. Lesions usually start on the abdomen and striae but may spread to the upper arms and thighs. The umbilicus may be spared. PEP is commoner in twin pregnancies. The rash is not associated with any maternal or fetal risk. PEP has recently been shown to be associated with low maternal serum cortisol levels.

Treatment is with reassurance, bland emollients and mild topical steroids. The rash disappears after childbirth.

Prurigo of pregnancy

Prurigo of pregnancy affects 1 in 300 pregnancies. It usually starts on the abdomen in the 3rd trimester but may persist for some months after delivery. Clustered excoriated papules (prurigo-like lesions) occur on the abdomen and extensor

surfaces of the limbs. The cause is unknown but pregnancy-related itch (pruritus gravidarum) may be due to cholestasis (p. 346). Rarely liver biochemical tests are abnormal and urinary HCG levels may be elevated. It can recur in subsequent pregnancies. Some authors believe the condition is associated with an increase in fetal mortality but this remains controversial.

Treatment is with topical steroids and oral antihistamines.

Pruritic folliculitis of pregnancy

This occurs in the 2nd or 3rd trimester of pregnancy and is characterized by an itchy folliculitis which looks similar to steroid-induced 'acne'. It is not associated with any increased maternal or fetal risk.

Treatment with topical benzoyl peroxide and hydrocortisone cream helps to relieve symptoms.

Pemphigoid gestationis (*herpes gestationis*)

This is the rarest of the pregnancy-related rashes (1 in 60 000). The immune changes of pregnancy appear to set off bullous pemphigoid. It is characterized by an itchy blistering urticated eruption that starts on the abdomen but may become widespread. Large bullae may be present. Unlike PEP it can occur early, starting in the 2nd or even 1st trimester of pregnancy, and the umbilicus is often involved. It tends to recur in subsequent pregnancies and at an earlier stage. Diagnosis is confirmed by immunofluorescence studies.

A transient bullous eruption occurs in 5% of infants, presumably due to transplacental passage of the offending antibody. There is no increase in fetal mortality but there is an increased incidence of prematurity and low birth weight which is probably due to the autoantibody causing placental insufficiency.

Treatment of mild cases is with potent topical steroids but most cases will require oral corticosteroids. The steroid dose may need to be increased after delivery as there is often a postpartum flare-up of the disease. The rash can be set off again by the oral contraceptive pill and this should be avoided.

PRINCIPLES OF TOPICAL THERAPY

Dermatology is unique in having such direct accessibility to the affected organ. This allows the use of topical treatments which can avoid certain systemic side-effects.

A topical therapy consists of an *active ingredient*, an appropriate *vehicle* or *base* to deliver this, and often a *preservative* or *stabilizer* to maintain the product's shelf-life. A cosmetically acceptable product is necessary and must be accompanied by instructions to the patients about correct usage as without this compliance tends to be poor. Perfumed or scented products should be avoided.

Bases and their uses

- **Creams.** A cream is a semisolid mixture of oil and water held together by an emulsifying agent. They need to have added preservatives such as parabens. They are 'lighter' and rub in more easily than ointments. They have a high cosmetic acceptability and are useful for topical treatments of the face and hands. Aqueous cream is particularly useful as a soap substitute.
- **Ointments.** These are semisolid and contain no water, being based usually on oils or greases such as

Human immunodeficiency virus and the skin

Dermatoses of pregnancy

Principles of topical therapy

Table 24.18 Emollients commonly used in the UK

Greasy emollients	Lighter creams
Epaderm ointment ^a	E45 cream ^a
Oily cream	Diprobase cream ^a
Unguentum Merck ^a	Aveeno cream ^a
50:50 white soft paraffin/liquid paraffin	Aqueous cream
^a Trade names.	

polyethylene glycol (water soluble) or paraffin (fatty). They feel greasy or sticky to the touch. They are the best treatment for dry, flaky skin disorders as they are good at hydrating the stratum corneum and they deliver an active ingredient (e.g. a steroid) more effectively.

If patients dislike the greasy nature of ointments, a cream is better than no treatment at all, but creams are less effective and do have to be used more frequently. A compromise may be to use a cream on the face and an ointment elsewhere (Table 24.18).

- **Lotions.** These are based on a liquid vehicle such as water or alcohol. They are usually volatile and rapid evaporation promotes a cooling effect on the skin. They are useful for weeping skin conditions and are ideal for use on hairy skin (e.g. the scalp). The cooling effect can be a useful antipruritic. Alcohol-based lotions should be avoided on broken skin as they cause stinging.
- **Gels.** These are semisolid preparations of high molecular weight polymers. They are non-greasy and liquefy on contact with the skin. They are useful for treating hairy skin (e.g. the scalp).
- **Pastes.** Pastes contain a high percentage (>40%) of powder in an ointment base. They are thick and stiff and difficult to remove from the skin. They are useful when a treatment needs to be applied precisely to a skin lesion without it smearing on to surrounding normal skin. An example would be dithranol in Lassar's paste (used on plaques of psoriasis) as dithranol will burn the surrounding normal skin.

Safety of topical steroids

Providing that preparations of appropriate strength are used for the body site being treated, these compounds can be used safely on a long-term intermittent basis (p. 1205). If potent steroids are misused, they will cause skin atrophy manifest as striae, wrinkling, fragility and telangiectasia.

Problems with topical therapies

- **Systemic absorption** may occur but only if very large areas of inflamed skin are treated topically and especially if the treatment is occluded with bandages or polyurethane films. Neonates are particularly susceptible to this owing to the relative increase in body surface area to volume.

- **Contact allergy** to topical preparations is not uncommon and may be suspected by unusually resistant disease or by apparent worsening of a condition after application of a substance. It is more common with creams as it is often the result of allergy to the preservative or emulsifying agent. Allergy can also be due to the active ingredient itself (e.g. neomycin or hydrocortisone).
- **Folliculitis** can occur due to blockage of hair follicles. Creams and ointments should be applied to the skin in the same direction as hair growth to try and prevent this blockage. It is a particular problem with the use of ointments in hot weather (especially if under occlusive bandages) and a lighter cream may be more appropriate at this time.
